SCHOOLS FOR X-RAY TECHNICIANS

The American Registry of X-Ray Technicians, which is sponsored by the American College of Radiology, requested the American Medical Association to assume the responsibilities of approving schools for x-ray technicians. A resolution embodying this request was presented to the House of Delegates of the American Medical Association during the 1943 session. Action on the resolution delegated the Council on Medical Education and Hospitals to establish standards of training, inspect schools and publish lists of approved schools. With the advice of the Registry and the College, suitable standards were prepared and during the 1944 session were accepted by the House of Delegates.

Prior to this time approval was granted by the Registry. All the schools on the 1944 list published by the Registry were surveyed before the standards, or "Essentials" as they are referred to by the Council, were finally adopted. This information as well as that obtained from other schools which were anxious to be approved has been tabulated and made available to the Registry, The first list of schools approved by the Council was printed in The Journal on Jan. 13, 1945.

There are 211 schools presently approved, which is an increase for the year of 50 schools. Thirty-two states and the District of Columbia are represented.

Only a relatively small number of the schools have entrance requirements beyond high school graduation, 174 of the schools accepting high school graduates. Fifteen schools accept graduate nurses. There are 18 schools that require one year of college and 17 that require two years of college for entrance.

No tuition is required by 133 of the schools. Thirty-one schools have a tuition fee of less than $100, and 35 others have fees ranging from $100 to $200.

Of the 211 approved schools, 137 offer twelve months of training, the percentage being approximately that of the previous year. Twenty-one schools offer courses of eighteen months, but 46 schools require twenty-four months of training and experience for completion of their course.

Maximum enrolment is 948, an increase of 184. There were 499 graduates reported, which is 72 more than last year and only 17 less than the anticipated number. It is expected that 660 students will be graduated next year.

Correspondence regarding schools for x-ray technicians should be addressed to the Council on Medical Education and Hospitals. Graduates desiring registration should communicate with the American Registry of X-Ray Technicians, 2900 East Minnehaha Parkway, Minneapolis 6.

APPROVED SCHOOLS FOR X-RAY TECHNICIANS

Council on Medical Education and Hospitals of the American Medical Association

NOTE: Complete details regarding admission to an approved school for x-ray technicians can be obtained by communicating directly with the radiologist. Asterisk (*) after name of school indicates that male as well as female students are admitted.

a. Three years of college academic work required for degree.
b. Tuition refunded at end of course.
c. Students are paid a stipend.
d. Degree given to University of Dayton affiliates.

SCHOOLS FOR MEDICAL RECORD LIBRARIANS

The American Association of Medical Record Librarians presented a formal resolution to the 1942 session of the House of Delegates of the American Medical Association requesting the latter to assume the responsibilities of approving schools for medical record librarians. Action on the resolution granted the Council on Medical Education and Hospitals authority to establish standards, inspect training programs and publish lists of approved schools. Minimum essentials were formulated with the assistance of the American Association of Medical Record Librarians after all existing schools were inspected. These essentials were officially accepted by the House of Delegates in 1943. The first list of approved schools was published in June 1943. Currently there are 12 schools on the approved list. One new approved school is included.

There were 63 students who completed the prescribed course during 1947. In addition, 10 students completed a special or short course which is given for experienced but untrained medical record librarians. Three schools offer these short courses with a reported enrolment of 12 students. This year's reports indicate a current enrolment of 59 students in the regular course and an anticipated graduation of 59 students. Two schools anticipate no graduates in 1948.

A satisfactory proficiency in shorthand and typewriting is a prerequisite for entrance to all schools. Nine schools require two or more years of college and seven of these admit graduate nurses. Three schools provide four year courses admitting high school graduates which lead to a degree. The Educational Board of the American Association of Medical Record Librarians has authority to review applications of persons who lack the college credits required by a school but have experience in the medical or business world. If the applicant's background of experience is satisfactory, the Educational Board can notify the school that the student is acceptable. These students, unfortunately, are not eligible for scholarships.

The length of the hospital training which includes the didactic instruction is twelve months. Tuition varies between $125 and $300, with an average of $170 and a mean of $150. The courses are arranged to issue a certificate or diploma after completion of the twelve month course, while 1 hospital and all university courses have facilities to offer a degree.

* All students are required to be proficient in typing and shorthand.
† Four academic years and one summer session.

The demand for adequately trained medical record librarians continues. Although the very considerable increase in the number of graduates this year over the 25 graduates of 1946 is gratifying, the fact remains that the present schools are not providing sufficient trained personnel to meet the needs of the hospitals. The scholarships that have been made available by the

National Foundation for Infantile Paralysis are doubtless of much help in increasing the enrolment. The inservice training programs provided through funds given by the Foundation together with the institutes sponsored by the American Hospital Association in cooperation with the American Association for Medical Record Librarians have been of valuable assistance.

Correspondence regarding registration should be addressed to the American Association of Medical Record Librarians, 18 East Division Street, Chicago 10.

SCHOOLS FOR OCCUPATIONAL THERAPY TECHNICIANS

At the 1933 sessions of the House of Delegates of the American Medical Association a resolution was introduced that some plans be effected for the establishment of standards, ratings and inspections of training schools for occupational therapy technicians. This program was referred to the Council on Medical Education and Hospitals, and all of the 13 existing schools were surveyed. The Essentials of an Acceptable School of Occupational Therapy were ratified by the House of Delegates of the American Medical Association at the Atlantic City session in 1935, such standards to become effective on Jan. 1, 1939. A report of the Council on Medical Education and Hospitals to the House of Delegates in 1936 contained the names of 4 schools which had already met these standards. There are currently 25 schools on the approved list, 7 new schools having been approved.

The 25 approved schools offer 36 curriculums, and 3 schools offer advanced courses. Entrance requirements vary according to the curriculum. Eighteen are designed for high school graduates who, it is expected, will devote four or five academic years to complete the combined college and professional subjects. Eight of the curriculums require one year of college as a prerequisite, while 2 prescribe two years of college credits and 7 require a degree.

There is a correlation between the length of training and entrance requirements among the various curriculums. Those that require a college degree usually enable the student to complete all work in two years, but 1 school presents three academic years of subjects in the course designed for college graduates.

All the approved schools are affiliated with recognized colleges, and 32 of the curriculums enable the student to acquire college credit. The amount of college credits available vary from about one semester in some of the shorter courses to 128 semester hours. Thus, degrees are granted by 23 schools and a diploma or certificate is presented by the other 2 schools. The curriculums which are shorter than the basic course are designed for a certificate or diploma when the student completes all requirements.

Tuition ranges between $21 and $600 per year. These amounts are, of course, determined by university fees, and there is no instance in which a certificate course fee exceeds the fee for a degree course. The fees for 10 courses have been increased by amounts varying from $25 to $125.

A total of 320 graduates have been reported by 19 schools with 74 students reported as having completed advanced courses at 10 schools. An equal number is anticipated to graduate from approved schools in 1948.

SCHOOLS FOR PHYSICAL THERAPY TECHNICIANS

The House of Delegates of the American Medical Association in 1934 requested that some plan be effected for the establishment of standards, ratings and inspections of schools for the training of physical therapy technicians. The Council on Medical Education and Hospitals assumed responsibility for this program and by 1936 had completed a survey of these schools. Certain minimum standards were formulated. These were presented to the House of Delegates of the American Medical Association and were ratified in May 1936. The first list of 13 approved schools appeared in THE JOURNAL in August 1936. Revisions have been published annually since that time.

There are 25 approved schools, with 1 new school approved in 1947. Twenty-one schools reported a total of 383 graduates of their regular courses. Ten schools offering advanced courses reported satisfactory completion of these courses by 20 students. The reports anticipate an approximately equal number of graduates in 1948.

Entrance requirements include graduates of accredited schools of nursing, graduates of physical education courses or collegiate training including science courses. Eighteen of the schools admit nurses, 15 accept physical education graduates and all but 2 of the schools will permit college students to enroll in the one year curriculum. The list of schools requiring college training for admission contains 14 that specify three years of college credits, 10 which mention two years of credits, and 4 that require a degree. A total of eight courses are combined with college curriculums, so that high school graduates can obtain a degree in physical therapy after four academic years of study. All but 7 of the schools offer college credits, although 2 schools which list two courses state that only one course will permit the student to accumulate college credit.

The length of training is twelve months in most instances, but 3 schools require fourteen, fifteen and twenty-four months respectively for the regular course, while high school graduates must complete the four year program.

---

* Courses are so arranged that any of the entrance requirements will qualify students for training. a = *Graduation from accredited school of* nursing; b = Graduation from accredited school of *physical education*; c = Two years of college with science courses; d = Three years of college with science courses; e = Four years of college with science courses. H.S. = High school graduation.

1. Male students are admitted.
2. High school graduates admitted to four-year course leading to degree.
3. Non-residents charged additional fee.

SCHOOLS FOR MEDICAL TECHNOLOGISTS

The original survey of 196 schools for medical technologists was published in The Journal, Aug. 29, 1936, together with the first list of 96 approved schools. Essentials had been formulated by the Council on Medical Education and Hospitals of the American Medical Association with the cooperation of the American Society of Clinical Pathologists and ratified by the House of Delegates of the American Medical Association in May 1936.

There are 337 schools reported in the current list with 45 states represented. This is an increase of 44 schools. One school was discontinued.

Concerning entrance requirements, 239 schools admit students who have completed two years of college subjects, 52 require three years of college preparation and 38 require a degree for admission. The requirements for admission to 4 schools are intermediate between two and four years.

The course length in 278 of the schools is twelve months. Of the remainder, 31 give courses of eighteen months, 14 of fifteen months and 8 of twenty-four months.

Of the 337 schools listed, 213 require no tuition, an increase of approximately 12 per cent. Excluding university fees, less than 5 per cent of the schools charge over $150 for the course. Approximately 100 independent schools have tuition fees and 28 more are required to collect university fees.

Certificates are issued by 204 schools on completion of the course. Diplomas are granted at 47 schools, and 73 schools have college or university affiliations which give their students a degree. Forty-seven schools offer no certifying instrument.

The maximum enrolment was 2,239, an increase over last year of 192. There were 1,206 graduates, which was 128 more than the previous year. It is anticipated that 1,582 students will be graduated next year.

Correspondence regarding schools for the training of medical technologists should be addressed to the office of the Council on Medical Education and Hospitals. Graduates of approved schools desiring registration should communicate with the Board of Registry of Medical Technologists, Ball Memorial Hospital, Muncie, Indiana.

APPROVED SCHOOLS FOR MEDICAL TECHNOLOGISTS

Council on Medical Education and Hospitals of the American Medical Association

NOTE: Under "Tuition" the letter B indicates that a breakage fee is charged; the letter U indicates university fees. Students lacking the scholastic requirements should contact the registrar of the college or university and not the hospital. Those who wish to enroll in a course given by the college or university or who desire to transfer their credits should correspond with the registrar and not the hospital.

EDITORIAL ANNOUNCEMENT

The compositors returned to work on Monday, June 28. This issue of The Journal has been prepared in part by the use of Vari-Typer machines.

HOSPITAL SERVICE IN THE UNITED STATES

Elsewhere in this issue is the 1947 hospital report of the Council on Medical Education and Hospitals which reveals an increase in hospital service during the past year in spite of a decrease in total bed capacity. For all registered hospitals the bed capacity decreased in 1947 to 1,425,222 from 1,468,714 in 1946; the average daily census also decreased from 1,239,454 to 1,217,229 during the same period. However, the number of patients admitted increased from 15,153,452 in 1946 to 15,829,514 in 1947. This apparent discrepancy is clarified when the average length of stay per patient in general hospitals is considered. In 1946 the average patient remained 12.9 days in a general hospital; in 1947 he was discharged after 11.4 days, a gain to the patient of a day and a half. The decrease in total bed capacity is accounted for entirely in the governmental group, federal hospitals alone reporting 51,282 beds less than last year. Nongovernmental hospitals, on the other hand, increased their number of beds by 9,037. With admissions to the governmental hospitals decreasing by nearly 394,000, admissions to civilian hospitals increased by over 1,000,000 for the second consecutive year. Births in hospitals registered by the American Medical Association passed the two million mark for the first time in 1946; during the current reporting period, births in these hospitals reached the still higher figure of 2,837,139.

The increase in the number of admissions was noted in all types of hospitals, with the exception of tuberculosis hospitals, convalescent hospitals and those classified as "institutions." Admissions to tuberculosis sanatoriums remained quite constant, with 99,741 admitted in 1946 and 99,080 in 1947. General hospitals contributed the largest share of the increased admissions, adding more than 600,000 to the previous year's figures; furthermore, 97 per cent of the births reported occurred in general hospitals.

Hospitals for nervous and mental diseases still account for more than half of the number of patients occupying hospital beds; in 1947, of an average census of 1,217,229 patients, 53.5 per cent were in hospitals of this type. General hospitals contributed 37.5 per cent of the total, while all other hospitals and related institutions made up the remaining 9 per cent. Beds in neuropsychiatric hospitals increased by about 6,000, while the capacity in general hospitals decreased by about 50,000.

It could perhaps have been anticipated that the percentage of beds occupied would rise; a slight increase, 1 per cent, was reported for all types. In the general hospital group, however, to which 92 per cent of patients was admitted, an actual decrease occurred, from 80.6 per cent in 1946 to 78.9 per cent in 1947. The over-all figure of 85.4 per cent occupancy for all hospitals represents an upper limit beyond which efficient administration would seem improbable. A safety factor of 15 per cent vacancy is considered minimal for expeditious handling of the patient load; a lower margin would undoubtedly mean protracted delays and lessened efficiency in admissions and patient control.

While the primary purpose of the modern hospital is to provide adequate facilities for the care and treatment of the sick, an increasingly important function is the hospital's role as an educational institution. The magnitude of the teaching program is evident in the number of hospitals offering training; 807 hospitals, primarily general, have approved intern programs, and 1,102 are approved for residency training. Nursing schools now number 1,212, with an additional 193 offering affiliating courses only. There are currently 12 technical schools approved for training medical record librarians, 25 schools for training technicians in physical therapy, 25 for technicians in occupational therapy, 211 schools for x-ray technicians and 337 engaged in training medical technologists. The conduct of these programs for training physicians, nurses and technical personnel involves a considerable expenditure of funds and a great many hours of time and effort from the hospitals participating. Nevertheless, the continued cooperation of these hospitals is essential in providing trained personnel to meet the ever increasing demand for more and better professional service.

INTERNSHIPS AND RESIDENCIES

Data published in the Internship and Residency Number of The Journal, May 1, make it apparent that the point is being reached in graduate training beyond which further expansion of facilities is probably not desirable. In hospitals approved for intern training, the number of positions available already exceed the number of applicants by 30 per cent. More than 12 per cent of approved hospitals were unable to fill any of their positions during the past year, with an additional 13 per cent having less than half the number of interns desired. Hospitals now approved for residency training are well able to accommodate future graduates, in most, if not all, of the specialties. While the number of approved residencies has increased threefold since prewar years, the number of applicants apparently is gradually decreasing. The majority of physicians who sought residencies after their release from military service have completed their training or will do so during the next year. Furthermore, the interest in specialty training among medical students is believed to be lessening. Can it then be assumed that the saturation point in training facilities of this type has been reached and that a further increase will probably result in the same problems now confronting hospitals approved for intern training?

The Council on Medical Education and Hospitals believes that approval should be extended to any hospital able to meet its educational requirements without any attempt to limit the number so designated; however, the responsibility of the Council to graduate physicians accepting appointments in approved hospitals requires critical evaluation in approving new hospitals and in reviewing those previously approved. Reevaluation of these programs has been accomplished in several of the specialties, in collaboration with the American Boards, and at an early date it will be done with the other specialties as well as in the intern field. Some hospitals where the survey revealed that the type of training had fallen below the required standard have completely reorganized their teaching programs; some have affiliated with other hospitals offering a more complete plan of training, and some programs have been discontinued. Similar changes probably will be made in the other residency fields and in hospitals approved for intern training.

Under the exigencies of the war period, ideal standards could not be maintained. However, those mitigating circumstances no longer exist and hospitals should have been able, by this time, to develop educational programs in accordance with acceptable standards. Those which fail to meet such requirements will not be able to attract their quota of interns or residents and will require reevaluation. Adequacy of supervision, qualifications of the house staff, adequacy of clinical material and sufficient necropsy material are basic criteria and cannot be overlooked in considering a hospital's ability to carry out an intern or residency program.

At this point, hospitals expecting to attract applicants and maintain an approved status must have reconverted to justify continued participation in training the future physician.

Current Comment

TECHNICAL PERSONNEL

The need for more technical personnel in hospitals, clinics and physicians' offices continues and in some quarters has been termed "critical." The relation between the number of admissions to hospitals and the requirement for full time trained technicians has been demonstrated by statistical comparison. Most hospitals, and many with greatly increased facilities through new construction, are operating at capacity. The present general tendency toward shorter periods of convalescence in hospitals has permitted a greater turnover of patients than in the past. Progressive advances in therapy, new methods of treatment and rehabilitation have created new demands for technical personnel. These demands have been further augmented by the increased needs of government hospitals, particularly those of the Veterans Administration. Federal agencies that are interested in maintaining adequate standards in the training of technical personnel share the general concern over the shortages and are actively engaged in measures designed to increase enrolment and encourage the development of new schools. The number of technical schools approved by the Council on Medical Education and Hospitals and the number of graduates from these schools have increased each year, but are still insufficient to meet current needs. The present lists of approved technical schools include seven new schools of occupational therapy, forty-four schools for clinical laboratory technicians and fifty new schools for x-ray technicians. Schools for physical therapists and for medical record librarians have not increased proportionately. The solution of the problem lies in increasing enrolment in presently approved schools to acceptable capacity and in the development of new schools by those universities, colleges and hospitals that can provide adequate facilities and qualified teaching personnel. These should be developed in accordance with the essentials for approval as outlined by the Council on Medical Education and Hospitals.

AGAIN THOSE SELECTIVE SERVICE STATISTICS

The report of the Brookings Institution on compulsory health insurance concludes that ". . . [Selective Service statistics] are unreliable as a measure of the health of the nation and cannot be used to show the extent of the medical needs of the country as a whole." This conclusion is based on certain characteristics of the draft data previously noted by Dr. Maurice H. Friedman in his testimony before the Senate Committee on Labor and Public Welfare. The arguments presented in the Brookings report are undeniably valid when applied to rejection rates; possibly data on the prevalence of recorded defects may be of some value as a guide to improvement if used with caution. In the May 1948 issue of the *Connecticut Health Bulletin,* William Haenszel and Edwin T. Tracy of the Bureau of Vital Statistics use Selective Service prevalence rates as a basis for estimating the incidence of certain defects in Connecticut. The Selective Service medical statistics bulletins do not contain data on prevalence of recorded defects by states; consequently, the prevalence rates for Connecticut were calculated by adjusting the national prevalence by the ratio of rejections reported for the nation and the state. The validity of this procedure rests on the assumption that the national rejection-prevalence index holds for the state, which would not be true if standards or the application of standards varied in different areas. National-state rejection ratios were computed for the period April 1942-December 1943; national prevalence rates for the same period were used except in the case of minor defects which were more completely recorded from November 1940 to September 1941. In 2 cases the resulting estimates of the incidence of defects among white men aged 20 to 34 in Connecticut could be checked against corresponding data from other sources. The method used in the article yielded a rate of 6.6 per thousand for syphilis as compared to 6.1 reported by the United States Public Health Service, while the estimated tuberculosis rate of 10.5 was in close agreement with the results of studies by the Tuberculosis Commission. Connecticut draftees were apparently above the national averages as to eyes, teeth and tuberculosis but inferior specimens of young manhood as to mental diseases and possibly ear defects. Although the apparent accuracy of two estimates does not establish the validity of their method, Haenszel and Tracy recommend their tables for use by public health workers in Connecticut pending the publication of more precise data. They suggest that the utility of selective service material could be increased by the inclusion of data on the incidence of defects by states, the revision of figures to relate to individuals rather than to examinations and an exposition of changes in procedures and standards and their effects on rejection and prevalence rates. If these suggestions were followed and if the data were used with an awareness of their limitations, Selective Service statistics might yet prove to be of practical as well as propaganda value.

CALCIUM-ENRICHED MEAT

McQuarrie and associates[1] of the University of Minnesota, compared the nutritional value of calcium-enriched ground beef with that of milk from the point of view of utilization of calcium, phosphorus and protein. By various additions the two diets were adjusted to contain the same quantities of protein, fat, carbohydrate, water, calcium, phosphorus and vitamins. Young litter-mate rats about 35 days of age were divided into two dietary groups, one receiving milk, the other cooked lean meat enriched with calcium gluconate and phosphates. The animals were maintained on these diets for six weeks. At the end of this period the animals were decapitated twenty-four hours after all food had been removed from their cages. Pooled blood samples were analyzed for calcium, phosphorus and serum protein. The femurs of half of the rats were weighed and analyzed. The entire carcass of each of the remaining rats was analyzed for calcium, phosphorus and total fat-free dry weight. The serum protein, calcium and phosphorus levels at the end of the experiment did not show significant differences attributable to differences in diet. All values were well within normal range. The data thus indicate clearly that the calcium-supplemented meat diet to supply calcium, phosphorus and protein was as good as milk. This conclusion was confirmed on 2 hospital patients, aged 12 and 14 years, who were placed on a milk-containing diet for fifteen days followed by a calcium-enriched meat diet for a similar period of time.

RAW VERSUS AUTOCLAVED SOY BEAN PROTEIN

In 1917 Osborne and Mendel[1] noted that rats fed raw soy bean flour grew more slowly than control rats fed the same flour after autoclaving. Subsequently, Ham and Sandstedt[2] offered an explanation for this nutritional difference, in their isolation of a trypsin-inhibiting substance from unheated soy bean flour. They found that this trypsin inhibitor had a retarding effect on the normal growth of chicks, presumably by reducing proteolytic activity in the small intestines. Bowman[3] demonstrated its in vitro inhibition on tryptic digestion of casein: Kunitz[4] afterward succeeded in isolating the soy bean tryptic inhibitor in crystalline form. Because of the widespread use of soy bean flour as human food, Lewis and Taylor[5] of the department of medicine, Harvard University, have compared the utilization of raw and autoclaved soy bean flours in man. Two cooperative and well-nourished patients were selected. Both were allowed unrestricted activity about the wards. Their caloric requirements were estimated at 2,500 calories. A basic diet was therefore planned to afford 2,500 calories daily. This diet provided a low protein intake of 25 Gm. from mixed sources.

After an initial period of eight days during which the subjects received only the basic diet, 188 Gm. of raw soy bean flour containing 75 Gm. of protein was substituted for an equal caloric value of carbohydrate in the basic diet. After a nine day period on raw soy bean flour the subjects were returned to the basic diet for six days. This was followed by another nine day period during which the subjects received 188 Gm. of soy bean flour previously autoclaved for one hour at 15 pounds pressure. Nitrogen balance and body weights were followed throughout the study. The average daily nitrogen retention of the 2 patients was 5.4 Gm. on the raw soy bean flour and 6.95 Gm. on the autoclaved flour. This indicates a 20 per cent nutritional superiority for the autoclaved material. The 2 patients showed an average daily stool nitrogen of 1.45 Gm. during both periods. The difference in the nutritional value of the raw and autoclaved material is therefore apparently not due to a difference in tryptic digestibility (trypsin inhibitor), but is presumably due to a difference in the metabolic availability of the resulting digestive products.

ORGANIZATION SECTION

Official Notes

NOTES ON THE SIXTH SEMIANNUAL MEETING OF THE MIDDLE ATLANTIC STATES REGIONAL CONFERENCE ON MEDICAL SERVICE

Organized about three years ago as a permanent unit in the conference program of the Council on Medical Service of the American Medical Association, the Middle Atlantic states group has met twice each year. The officers are: Dr. Francis F. Borzell, chairman, Philadelphia; Dr. Frederic J. Quigley, vice chairman, Union City, N. J.; and Dr. William Bates, secretary-treasurer, Philadelphia.

The sixth session was devoted primarily to the discussion of two topics: (1) the relationship between medical care plans and the Blue Cross and (2) the problem of developing county health units. In addition, Dr. James C. Sargent, of Milwaukee, spoke on the subject of National Emergency Medical Service, and Dr. Joseph S. Lawrence, Director of the Council on Medical Service, Washington Office, talked on the "Washington Horoscope."

The relationship between medical care plans and Blue Cross was presented by L. Howard Schriver, M.D., president, Associated Medical Care Plans, and E. A. Van Steenwyk, executive director of the Hospital Service of Philadelphia. Dr. Elmer Hess, member of the American Medical Association Council on Medical Service and president of the Medical Society of the State of Pennsylvania, led the discussion. Dr. Schriver outlined the creation of Associated Medical Care Plans and its functions and the recent developments in the field of joint cooperation between this organization and the Blue Cross. He presented the following common problems that exist for both groups and which should be one of the functions of any agency or national association evolving from this cooperation: (1) public relations, (2) advertising, (3) actuarial services, (4) enrolment, (*a*) reciprocity of contract coverage to subscribers, (*b*) transfer technic, (*c*) uniformity of basic contract features and (*d*) national employer enrolment and (5) assistance to member plans in any other capacity.

Mr. Van Steenwyk spoke of the teamwork necessary to satisfy the public and emphasized the need for bringing both medical and hospital programs together. In regard to developing team play, he suggested: (1) a single rate to employers for employees wherever employed, (2) standard administrative regulations, (3) a device which will provide similar coverage everywhere, (4) the need for a single agency through which employers may transact all business, (5) a device for providing standard benefits and (6) uniformity of public relations activities.

In opening the discussion, Dr. Hess pointed out that the first duty is to the American people and the second duty is to provide adequate medical care at a price that they can afford. Without the medical profession no adequate medical program is possible. He further pointed out that any general basic changes in policy covering medical care plans should have the approval of the American Medical Association Council on Medical Service before they are adopted.

A representative from each state was then called on to present his ideas on the subject.

Dr. Erval Coffey, medical director of the United States Public Health Service, opened the discussion on developing county health units. He stressed the idea that if local health units were properly organized the federal government would have no reason for many of its public health activities. Five basic reasons were given for the slow progress in developing county health units: (1) lack of medical personnel, (2) lack of qualified auxiliary personnel, (3) lack of incentive in this type of work, (4) lack of encouragement by medical schools and (5) lack of legislation.

Dr. James C. Sargent told of the activities of the American Medical Association Council on National Emergency Medical Service and the problems with which the Council must cope. He outlined the arguments against the drafting of physicians and urged state and county medical societies to activate at once a program for the civilian population to operate in the event of disaster.

In presenting the "Washington Horoscope," Dr. Lawrence selected a number of bills of interest to the medical profession and told of their present status.

Washington Letter

(From a Special Correspondent)

Aug. 11, 1948.

Report on Physiologic Studies

The Office of the Air Surgeon, U. S. Air Force, has received a report on the first nine months' operation of a special mission sent to Alaska last September to conduct studies on effects of cold weather on physiologic function. Colonel Jack Bollerud, who headed the expedition, based near Fairbanks, presented the report. Twenty-two enlisted men and seven officers, four of whom were physicians or allied scientists, made up the expedition. One of the group's findings was that during January the cold pressor response to immersion of the hand in ice water is reduced to only a slight blood pressure elevation, while in May it returns to two thirds of the elevation experienced at subtropical Randolph Field. Normal heat loss of the hand through conduction and radiation, as measured by a hand calorimeter, decreases appreciably in winter, it was found.

Civil Service Issues New Call for Physicians

The U. S. Civil Service Commission has broadcast a new call for medical officers, who are needed to fill positions in all sections of the United States. Vacancies exist in the Panama Canal Service, Indian Service, Department of the Army, Public Health Service, Veterans Administration, Civil Aeronautics Administration, Railroad Retirement Board, Children's Bureau and miscellaneous federal agencies. Entering salaries range from $4,479 to $6,235 per annum. Application forms are obtainable at first and second class postoffices and regional offices of the Civil Service Commission, as well as at Commission headquarters in Washington.

Certification of Specialists in Preventive Medicine

Medical officers of the Army, Navy and Public Health Service who believe that they can qualify as specialists in preventive medicine are now being invited to submit their applications to Dr. E. L. Stebbins, chairman, Interim Board of Preventive Medicine, % Division of Research Grants and Fellowships, National Institutes of Health, Bethesda, Md. The Interim Board is a step toward what the three services hope will be ultimate establishment of an American Board of Preventive Medicine.

Army Medical Department Marks 173rd Birthday

Professional and economic attractions of a military medical career are greater today than ever before, Army Surgeon General Raymond W. Bliss asserted on the occasion of the Army Medical Department's one hundred and seventy-third birthday anniversary July 27. Its burden increased by reenactment of Selective Service, the department will require 3,900 more volunteer medical officers by June 30, 1949, said Gen. Bliss. Foremost among professional inducements, he declared, are the opportunities now offered to Army physicians to take graduate training toward specialty certification.

Dr. Walter Bauer in Charge of Rheumatic Disease Survey

Dr. Walter Bauer, of Boston, has been appointed head of a committee which will undertake to survey research which is being conducted in arthritis and other rheumatic diseases. The announcement was made by Dr. Lewis Weed, chairman of the National Research Council's Division of Medical Sciences, which was asked by the American Rheumatism Association to sponsor the survey.

GOVERNMENT SERVICES

SECRETARY OF DEFENSE

INTEGRATION OF PANAMA CANAL ZONE HOSPITAL SERVICES

On recommendation of the Committee on Medical and Hospital Services of the Armed Forces, Secretary of Defense James Forrestal has approved integration of National Military Establishment hospital and medical services in the Panama Canal Zone area. By this action, hospitalization of the personnel of all three services on the Atlantic side of the Canal Zone is assigned to the Navy, while on the Pacific side hospitalization for all three services is assigned to the Army. One of the two hospitals heretofore maintained by the Army for its military personnel will be closed, together with one of three now caring for civilians employed on the Canal. Better common use of the medical staffs of the three services also will be made by establishing a Panama Area Joint Medical Advisory Committee composed of representatives of the three armed forces and of the Panama Canal Administration Medical Service. The chairman will serve as medical director on the staff of the Commander-in-Chief, Caribbean Command. Under the plan, use will be made of medical experts of any service for special duty in any medical activity where their skills are needed temporarily.

The two hospitals to be closed are the Fort Gulick (Army) and the Margarita (Panama Canal Administration) hospitals, both on the Atlantic side. The Fort Gulick Hospital will be used solely as a dispensary. The Margarita Hospital will be closed and retained in a maintenance status.

The Gorgas Hospital at Balboa will continue to be operated by the Panama Canal Administration to hospitalize and provide outpatient service on the Pacific side for civilian employees of the Panama Canal and the Panama Railroad, and other civilians for whom medical treatment is authorized by law, regulation or treaty. About 70,000 civilian workers other than employees of the military establishment, together with their dependents, are entitled by contract to medical services and hospitalization. In addition, treaty obligations admit citizens of certain South and Central American countries to the Gorgas Hospital, which will continue to provide specialized clinical pathology and central laboratory facilities and services beyond the scope of the other medical installations in the Canal Zone, together with specialized consultative, diagnostic and treatment services for special cases.

The Committee on Medical and Hospital Services, of which Dr. Paul R. Hawley, formerly Chief Medical Officer of the Veterans Administration, is chairman, was appointed by Secretary Forrestal to make a study of these services with recommendations for coordination, efficiency and economy. In addition to Dr. Hawley, the members of the committee are Major General Raymond W. Bliss, Surgeon General of the Army; Rear Admiral Clifford A. Swanson, Surgeon General of the Navy, and Major General Malcolm C. Grow, the Air Surgeon. Rear Admiral Joel T. Boone is executive secretary of the committee.

ARMY

CONSULTANTS ARRIVE IN VIENNA

Headquarters, United States Forces in Austria, report that the sixth group of civilian consultants to the Surgeon General of the Army was scheduled to arrive in Vienna July 10 for a tour of medical installations throughout the European command. The consultants in the group are: Drs. Garfield G. Duncan, Philadelphia (internal medicine); R. A. Stiefel, Battle Creek, Mich. (surgery); A. James French, Kansas City, Mo. (pathology); Thomas N. Leonard, Washington, D. C. (obstetrics and gynecology), and Sydney G. Margolin, New York (neuropsychiatry). Among other places, they were to visit the 110th Station Hospital to examine unusual cases and assist in advanced training of the younger medical officers. They were scheduled to leave Salzburg July 13 to continue the tour.

RETIREMENT PROVISION FOR RESERVE OFFICERS

The 80th Congress passed a law, which was signed by the President, providing that reserve officers of any of the armed forces who have completed twenty or more years of acceptable membership may retire with benefits after they reach the age of 60 years, the retirement pay being computed at 2½ per cent of base pay for the highest rank held multiplied by the number of years on active duty, plus 0.5 per cent of the same base pay multiplied by the number of years on inactive status. These provisions may amount to as much as 75 per cent of the highest active duty pay drawn by the person receiving the allowances.

MEDICAL MEETING IN KOREA

At the regular monthly meeting of Army medical officers in Korea June 25 at the 382d Station Hospital, Lieut. Merrit F. Garland read a paper on anesthesia in emergency surgery and Lieut. Douglas MacInnis read a paper on "Acute Injuries of the Knee." Captain Mary Murphy of the Army Nurse Corps discussed the graduate courses recently given Korean nurses, and Chaplain Richard W. Jungfer discussed the role of the hospital chaplain in present day hospital care. During the afternoon the seventy-five Medical Department officers and twenty civilian doctors and nurses present held departmental conferences and made ward rounds discussing cases and diagnostic problems. A buffet supper and social meeting was held at the Officers' Club.

SELECTED FOR POSTGRADUATE TRAINING

The Surgeon General announces that the University of California Medical School has accepted Col. Lawrence C. Ball for a course in anatomy starting August 1 and that Capt. Irvin C. Plough has been accepted as a resident in internal medicine at the Goldwater Memorial Hospital, Welfare Island, New York. The following medical officers have been selected to pursue a course of training in orthoptics at George Washington University Medical School, Washington, D. C.: Cols. W. F. Cook, John B. Coates Jr. and Austin Lowrey Jr.; Lieut. Cols. Forrest E. Hull and Robert Lehman; Majors Francis W. Lanard and John J. Maloney; Capt. Joseph J. G. Gulyach, and First Lieuts. Stephen S. Eganbati, Harry W. Gray, Henry F. Jacobius, John B. Marley, Allen G. Thomas and Arnold Topilow.

ALLOCATE ARMY HOSPITAL BEDS FOR VETERANS

The Surgeon General has announced that 3,305 beds in Army hospitals throughout the United States have been allocated at the request of the Veterans Administration for the treatment of veterans, 325 of which were set aside specifically for cases of tuberculosis at Fitzsimmons General Hospital in Denver.

NAVY

OFFICERS APPROVED FOR POSTGRADUATE TRAINING

The Advisory Board of the Bureau of Medicine and Surgery has nominated the following medical officers for postgraduate training:

Comdr. Harry B. Eisberg: One year additional training in Orthopedic Surgery, Naval Hospital, Bethesda, Md.

Comdr. Rodney R. Gleysteen: Course in Public Health (Tropical Medicine), Johns Hopkins University School of Hygiene and Public Health.

Comdr. Leo W. Olechowski: Fellowship in Surgery, Northwestern University (Cook County Hospital).

Lieut. William W. Miller Jr.: Residency in Urology, Naval Hospital, Bethesda, Md.

Lieut. Donald R. Davis: Residency in Obstetrics and Gynecology, Naval Hospital, Oakland, Calif.

Lieut. (jg) Paul K. Hamilton: Residency in Pathology, Naval Hospital, San Diego, Calif.

Lieut. (jg) Robert L. Hill: Residency in Internal Medicine, Naval Hospital, Long Beach, Calif.

Lieut. (jg) Robert C. Kessler: Residency in General Practice, Naval Hospital, Portsmouth, Va.

Lieut. (jg) George J. Taylor, III: Residency in Obstetrics and Gynecology, Naval Hospital, San Diego, Calif.

NEW REGULAR OFFICERS

Lieutenants (jg) William F. Bennett Jr., of Columbus, Ga., George M. Rugtiv of Estherville, Iowa, and William K. Woodard of Hollis, N. H., have transferred to the Regular Corps of the Navy from an active reserve status. All three were graduates of the Navy V-12 training program.

Lieutenants (jg) Robert H. Lanfersieck of Sidney, Ohio, and John P. Rynd of Westfield, N. Y., have reported for active duty in the Medical Corps Reserve.

Commander Berger Thomas of Columbus, Ohio, and Lieutenant (jg) Frank D. Fuller of Reno, Nev., have reported for active duty from an inactive reserve status.

Commander Marcos A. Godinez and Lieut. Commander John R. Bierley, both of Puerto Rico, have joined the Medical Corps of the Regular Navy and been ordered to the Naval Station at San Juan for duty.

NEW NAVY INTERNS

The following men are newly accepted interns in the grade of lieutenant (jg) in the Medical Corps of the Navy: Walter J. Berger Jr., Madison, Wis.; George V. Branigan Jr., Glen Rock, N. J.; Carl A. Broaddus Jr., Newton, Va.; Louis F. Brignac Jr., Bogalusa, La.; Richard J. Broggi, Chelsea, Mass.; Kendall W. Caldwell, Philadelphia; Harry H. Dinsmore, Barnesboro, Pa.; George F. Elsasser Jr., Portsmouth, Va.; Warren C. Evans, Norfolk, Va.; Andrew W. Gibbons, Syracuse, N. Y.; George S. Haas, Los Angeles; Richard W. Heffner, Beaver Dam, Wis.; Philip P. James, Hampton, Va.; Erwin M. Janzen, Louisville, Ky.; J. W. Johnson, Ridgefarm, Ill.; Hoyt Kirkpatrick, Arlington, Va.; Robert N. Maurer, Teaneck, N. J.; John P. McNally, Philadephia; Norman K. Noordhoff, Chico, Calif.; Donald J. Perry, Houston, Texas; Maurie D. Pressman, Philadelphia; Don C. Rudeen, Los Angeles; William R. Stackable, Chicago; Benjamin C. Stigall, Louisville, Ky.; Charles C. Strong, Chehalis, Wash.; William E. Taylor, Pomeroy, Iowa, and Samuel E. Trueblood, Oswego, Ore.

ASSIGNMENT OF RESIDENTS

The following medical officers have been nominated for the residency training as indicated:

Comdr. John W. Albrittain, LaPlata, Md., dermatology and syphilology, at Naval Hospital, St. Albans, N. Y.

Comdr. Clement D. Burroughs, Little Rock, Ark., ophthalmology, Naval Hospital, San Diego, Calif.

Comdr. Henry J. Hunter, Oil City, Pa., obstertics and gynecology, Boston Lying-in Hospital and the Free Hospital for Women, Brookline, Mass.

Lieut. Chester M. Lessenden Jr., Lawrence, Kan., dermatology and syphilelogy, Naval Hospital, St. Albans, N. Y.

Lieut. (jg) Leland C. Brannon, Piedmont, Calif., surgery, Naval Hospital, Long Beach, Calif.

Lieut. (jg) Byron T. Eberly, Lancaster, Pa., otolaryngology, Naval Hospital, Philadelphia.

Lieut. (jg) Robert J. Fleischaker, Pittsburg, Kan., surgery, Naval Hospital, Chelsea, Mass.

Lieut. (jg) Carl N. Haggard, Oakdale, La., pediatrics, Naval Hospital, Philadelphia.

Lieut. (jg) Paul K. Hamilton Jr., Birmingham, Ala., pathology, Naval Medical Center, Bethesda, Md.

Lieut. (jg) Andrew M. Margileth, Cincinnati, Ohio, pediatrics, Naval Hospital, Chelsea, Mass.

Lieut. (jg) Robert E. Walsh, Elmira, N. Y., anesthesia, Naval Hospital, St. Albans, N. Y.

Lieut. (jg) Alan D. Watson, Kent, Conn., dermatology and syphilology, Naval Hospital, St. Albans, N. Y.

Lieut. (jg) Robert G. Williams Jr., Wenonah, N. J., internal medicine, Naval Medical Center, Bethesda, Md.

VETERANS ADMINISTRATION

FOLLOW-UP PROGRAM FOR TUBERCULOSIS CASES

The Veterans Administration has established a comprehensive follow-up program to prolong the effects of hospital treatment of veterans suffering from tuberculosis, of whom there are now more than 13,000 under the care of Veterans Administration, while a total of 80,763 veterans are receiving compensation or pensions for tuberculosis. The new follow-up program is designed to discover early any relapses among the tuberculous patients so that further treatment may be started promptly. Each veteran-patient before discharge from the hospital will be advised what to do to assist in keeping the disease under control, and he will be urged to report at regular intervals for sputum examinations and roentgen or other necessary studies. While veterans with service-connected tuberculosis can be handled in the outpatient departments of Veterans Administration offices or hospitals, they may obtain the services of qualified physicians or recognized institutions near their homes for this follow-up care if authorized to do so beforehand by the Veterans Administration.

PERSONAL

Dr. C. B. Spruit of the headquarters office in Washington was recently awarded the honorary degree as doctor of science by Illinois College, Jacksonville, Ill., where he was graduated; he later went to Harvard University Medical School. During World War II Dr. Spruit was deputy to the chief surgeon of the European Theater of Operations, Major General Paul R. Hawley. He was retired from the Army Medical Corps with the rank of brigadier general in 1946 after thirty years of service.

Dr. Karl Menninger has resigned as manager of the Veterans Administration hospital at Topeka to become chairman of the dean's committee and senior consultant to the hospital. His successor is Dr. Frank Casey, who has been chief of professional services at the Topeka hospital since 1946.

Dr. Glenn Drewyer, formerly of Bay City, Mich., has joined the staff of the Veterans Administration hospital at St. Petersburg, Fla. Dr. Drewyer served four years in the Navy in World War II and formerly was medical director of the Glenwood Hot Springs Clinic, Glenwood Springs, Colo.

NEW STAFF MEMBERS AT ROCHESTER

The following nine physicians recently joined the staff at the recently enlarged Veterans Administration Clinic in Rochester, N. Y.: Harry S. Wieder, Louis N. Kerstein, Hans Neuberg, Louis Singer, James J. Clements, William Libertson, Robert A. Wise, William R. Webster and Jacob Sirkin. Dr. Stephen Mayka resigned from the staff of the clinic June 30 to accept a fellowship at the Strong Memorial Hospital, Rochester.

Medical News

(Physicians will confer a favor by sending for this department items of news of general interest: such as relate to society activities, new hospitals, education and public health. Programs should be received at least two weeks before the date of meeting.)

DISTRICT OF COLUMBIA

Grant to Aid Patients With Intractable Asthma.—The George Washington University Hospital has received a grant from the Marcelle Fleischmann Foundation, Baltimore, for $1,000 to hospitalize patients with intractable asthma. Persons suffering from this type of asthma may apply to the George Washington University Hospital, Department of Surgery.

Cancer Research.—The American Cancer Society has granted $50,000 to George Washington University for cancer research through the Warwick Memorial. The Warwick Memorial earlier this year established a cancer detection clinic at the new George Washington University Hospital and research facilities. The $50,000 gift will be used to augment research activities.

ILLINOIS

Short Courses on Poliomyelitis.—The Illinois State Department of Public Health announces that physicians, nurses and physical therapists of Illinois are eligible for admission to the short courses in poliomyelitis being offered at the City Hospital in Cleveland during August and September. These courses, which are sponsored by the National Foundation for Infantile Paralysis, consist of lectures, demonstrations, conferences, discussions and practical applications. Two ten day courses are open for physicians; one began August 2, and another will start August 30. The courses for nurses and physical therapists, which are of two weeks' duration, open August 3 and September 13. There is no fee for the courses. Applications should be addressed to Dr. John A. Toomey, Department of Contagious Diseases, City Hospital, Cleveland, or to the National Foundation for Infantile Paralysis, 120 Broadway, New York.

X-Ray Unit Available at State Fairs.—A mobile x-ray unit from the state department of public health will be available at a number of county fairs in Illinois this summer and at the state fair in Springfield, August 13-22. The unit will be at the following county fairs: Adams County, Mendon, August 9-12; Brown County, Mt. Sterling, August 3-6; Oblong, Crawford County, September 6-10; Augusta Community Fair, August 31-September 3; Henderson County, Stronghurst, August 17-20; Knox County, Knoxville, August 10-13. Any person attending the fair may receive a roentgenogram of the chest. This service is part of the tuberculosis case-finding program conducted by the division of tuberculosis control in its effort to detect tuberculosis in its early stages. The film is later developed, interpreted, and the results sent in a confidential report to the person and his physician. Dr. Clifton F. Hall, Springfield, chief of the division of tuberculosis control, points out that tuberculosis remains one of the leading causes of death in Illinois.

Chicago

Dr. Knisely Awarded Alvarenga Prize.—In recognition of his studies on "Sludged Blood" the College of Physicians of Philadelphia on July 14 awarded the Alvarenga Prize for 1948 to Melvin H. Knisely, Ph.D., associate professor of anatomy, University of Chicago School of Medicine. The Alvarenga Prize was established by the will of Pedro Francisco da Costa Alvarenga of Lisbon, Portugal, an associate fellow of the College of Physicians of Philadelphia. The college invites the recipient to deliver the Alvarenga Lecture. Dr. Knisely became head of the department of anatomy at the Medical College of the State of South Carolina, Charleston, July 1.

Society News.—At the annual meeting of the Chicago Society of Internal Medicine May 24, Dr. George H. Coleman was elected president and Dr. Ernest G. McEwen, Evanston, secretary-treasurer.——At the annual meeting of the Chicago Gynecological Society, Dr. Herbert E. Schmitz was installed as president and Dr. Eugene A. Edwards was chosen president-elect; Dr. Edward M. Dorr was elected secretary, and Dr. Fred O. Priest was elected treasurer.

The Capps Prize in Medicine.—The Institute of Medicine of Chicago offers a prize of $400 for the most meritorious investigation in medicine or in the specialties of medicine. The investigation may be also in the fundamental sciences, provided the work has a definite bearing on a medical problem. Competition is open to graduates of Chicago medical schools who completed their internship or one year of laboratory work in 1946 or thereafter. Manuscripts must be submitted to the secretary of the Institute of Medicine of Chicago, 86 East Randolph Street, Chicago 1, not later than Dec. 31, 1948. The manuscript of the prize paper is to become the property of the Institute of Medicine of Chicago. If no paper presented is deemed worthy of the prize, the award may be withheld at the discretion of the Board of Governors.

INDIANA

State Health Officer Honored.—Dr. Leroy E. Burney, Indianapolis, who has served three years as state health commissioner, was awarded a plaque and a certificate by the Indiana Chamber of Commerce in recognition of his work for the state department. The award is known as the Good Governmental Award.

University Expansion Projects.—Two major construction projects have been approved for the Indiana University Medical Center, Indianapolis, including expansion of the department of radiology and erection of a research wing to the James Whitcomb Riley Hospital for Children. The addition to the department of radiology will add 5,600 square feet of floor space. The research wing, for which the state has allocated funds, will provide laboratories for research into children's diseases. The Riley Memorial Association has approved a grant of $250,000 in support of research over a period of five years.

MICHIGAN

Rabies Control.—A total of 163 new cases of rabies and 1 human death this year shows the urgent need for local rabies control measures. To aid in the control of rabies, the Michigan Department of Health and the Michigan Department of Agriculture have prepared a pamphlet "Protect Yourself, Your Family and Your Dog Against Rabies." Local rabies control committees are being organized in several counties; ten counties are under dog quarantine, and five counties require vaccination of dogs before licensing. Similar protection is needed in all the thirty-four Southern Michigan counties in the rabies danger area. The pamphlet is available without charge from the local health departments or the Michigan Department of Health, Lansing 4.

NEW YORK

Cardiac Research.—The U. S. Public Health Service has granted Harold C. Wiggers, Ph.D., professor of physiology and pharmacology, Albany Medical College, $7,600 for one year's research on the heart and the circulation of blood. He will be assisted by Drs. Edward Sharkey and G. Rehmi Denton, and Harold Goldberg, M.S.

Postgraduate Instruction.—The Medical Society of the State of New York, with the cooperation of the New York State Department of Health, has arranged postgraduate instruction for a joint meeting of the Syracuse and Utica Academies of Medicine, September 16, 8 p. m., at the Rome Country Club, Rome. Dr. Floyd S. Winslow, Rochester, will speak on "The Doctor on the Witness Stand."

New York City

University Appointment.—Dr. H. Houston Merritt, chief, division of neuropsychiatry at Montefiore Hospital, has been appointed professor of neurology and executive officer of the department at Columbia University College of Physicians and Surgeons, and director of the neurologic service of the Neurological Institute of Presbyterian Hospital. Dr. Merritt is a graduate of Johns Hopkins University School of Medicine, Baltimore.

New Director of Vanderbilt Clinic.—The Board of Trustees of Presbyterian Hospital has named Dr. Joseph Earl Snyder director of Vanderbilt Clinic. Caring for over 300,000 patients a year, the clinic is the outpatient department for the voluntary hospitals of the Columbia-Presbyterian Medical Center. Dr. Snyder was graduated from the University of Pennsylvania School of Medicine, Philadelphia, 1943, and after an internship became chief resident in pathology and administrative assistant at the Hospital of the University of Pennsylvania. During World War II he served as a radiologist at the separation center, Camp McCoy, Wis., and as chief of laboratory and pathologist to the 6th Service Command at Gardiner General Hospital, Chicago. After the war Dr. Snyder returned to the Graduate Hospital of the University of Pennsylvania, where he has been assistant director under Dr. Robin C. Buerki.

OHIO

Personal.—The 1948 Lower Fellowship Thesis Prize was awarded on June 15 to Dr. Alys H. Lipscomb, Cleveland, for her paper, "Incidence of Various Types of Essential Hypertension as Related to Evaluation of Successful Therapy."

Appoint Head of Ophthalmology Department.—Dr. Roscoe J. Kennedy has been appointed head of the department of ophthalmology at the Cleveland Clinic. Dr. Kennedy joined the clinic staff in 1937. He was graduated from the State University of Iowa College of Medicine, Iowa City, 1931. During World War II he served four years with the medical corps of the U. S. Navy in the Southwest Pacific.

SOUTH DAKOTA

Appoint Superintendent of State Board.—Dr. Gerald J. Van Heuvelen, Pierre, was appointed to succeed Dr. Gilbert Cottam, Pierre, retired, as superintendent of the South Dakota State Board of Health, effective July 1. Dr. Van Heuvelen received his M.D. degree from Rush Medical College, Chicago, in 1932.

Course for Medical Technicians.—Facilities for training students in medical technology have been expanded at the University of South Dakota School of Medical Sciences, Vermillion. Sacred Heart Hospital and Sioux Valley Hospital, Sioux Falls, are also cooperating with the medical school in this training. The medical school is developing plans also to establish a curriculum in x-ray technology in cooperation with the aforementioned hospitals. This course will be open for the first time this fall to students wishing to prepare themselves for a career in x-ray technology.

TEXAS

State Medical Election.—Officers of the State Medical Association of Texas for the coming year are Dr. Tate Miller, Dallas, president; Dr. George V. Brindley, Temple, president-elect; Dr. Thomas H. Thomason, Fort Worth, treasurer, and Dr. Harold M. Williams, Fort Worth, secretary-editor.

Workshop for Cardiac Patients.—The Galveston County chapter of the Texas Heart Association has planned for hospital patients with cardiac disease a workshop designed to give training in various handcrafts which might lead to employment for persons whose heart conditions prevent them from returning to previous jobs.

Dr. Kemp Comes to Baylor University.—Dr. Hardy A. Kemp, dean of Wayne University College of Medicine, Detroit, has been named professor of preventive medicine and chairman of the department of public health and preventive medicine at Baylor University College of Medicine, Houston. He will assume these duties in September. Dr. Kemp served on the faculty at Baylor from 1928 until 1939, when he became dean and professor of preventive medicine at the University of Vermont College of Medicine, Burlington, Vt. During World War II he was a colonel in the army medical corps. He has been dean of the school of medicine at Wayne University since 1945.

WEST VIRGINIA

New Hospital License Law.—Applications for license under the new state hospital licensing law have been received by the state health department from one hundred and nine of the one hundred and fifty-two known institutions caring for the sick and injured. The deadline for submission of applications expired July 1. The report compiled by the health department showed that applications have not been filed by nine general hospitals, six doctors maintaining offices with five or more beds, two osteopathic hospitals and twenty-five nursing and alcoholic homes.

Dr. Gaydosh Honored.—Dr. Michael Gaydosh, Wheeling, has been chosen by Slovak V. Amerike as the American Slovak Father for 1948. Dr. Gaydosh was advised of his selection, in part, as follows: "This special honor was bestowed for your unselfish work for humanity performed as one of the oldest American doctors of Slovak descent. Your sacrifices and endeavors in the field of medicine and fraternalism merit special recognition." Dr. Gaydosh came to this country from Czechoslovakia. After working his way, he received his M.D. degree from the University College of Medicine, Richmond, Va. He opened offices in Wheeling in 1905 and has continued to practice there. Dr. Gaydosh has served as supreme medical examiner for the First Slovak Catholic Union for the past thirty years. He is also a member of the executive board of the Slovak League of America.

Resume Motherhood Correspondence Course.—Resumption of the "Motherhood Correspondence Course" is about to be undertaken by the state health department, and letters concerning the availability of this service to all practitioners and health departments are being mailed to component societies of the state medical association. The purpose is to help physicians reduce the heavy loss in unborn and newly born babies, which finds West Virginia fourth from the bottom in infant mortality among all states and territories. The course before World War II was used by mothers on recommendation of their family doctors. Over 12,000 West Virginia women took advantage of the service in 1943, the last year that it was in operation. Statistics show that 69 per cent of all infant deaths in West Virginia during the past three years have been due to prenatal, natal and immediately postnatal causes. Within the past five years the increase of these deaths has totaled nearly 10 per cent. A recent study made by the state health department discloses not more than twenty-five full time obstetricians in this state, mostly in the larger cities.

WISCONSIN

The Godfrey Scholarship.—A trust fund, to be known as the Dr. Rush C. Godfrey Medical Scholarship Fund, has been established by Mrs. Rush C. Godfrey of Lancaster in honor of her late husband, who died April 14, 1947. Interest from the fund will be used for the education of a boy or girl in the practice of medicine.

Symposium on Steroid Hormones.—A symposium on steroid hormones will be held at the University of Wisconsin Medical School, Madison, September 6-8, as a part of the centennial celebration of the Wisconsin State University. Scientists from many universities and medical schools throughout this country, England and Canada are on the program. This symposium will be open to the public and physicians, chemists and scientists from other fields are invited to participate. No registration fee is to be charged. Reservations for board and room, available in Elizabeth Waters Hall on the Wisconsin campus at $16.25 for the three day period, may be made with Dr. Henry A. Lardy, Department of Biochemistry, University of Wisconsin, Madison 6.

GENERAL

Personal.—Dr. Charles S. Cameron, medical director of the American Cancer Society, announces the appointment of Dr. Thomas F. Nealon Jr., Jessup, Pa., as assistant director of the service division of the society. Dr. Nealon received his M.D. degree from Jefferson Medical College of Philadelphia, 1944, under the U. S. Naval Reserve program. Following separation from the Navy, he engaged in general practice at Olyphant, Pa.

Award of Remington Medal.—Andrew G. DuMez, Ph.D., Baltimore, dean, University of Maryland School of Pharmacy, will receive the Remington Medal this fall. This gold medal commemorates Joseph P. Remington, pharmacist, who was chairman of the U. S. P. Revision Committee for several decades. Since the establishment of the American Council on Pharmaceutical Education in 1932, Dr. DuMez has served as secretary-treasurer, being primarily responsible for painstaking analysis of records of performance by all colleges of pharmacy, supervision of inspection schedules, formal rating of colleges and the task of dealing with educational authorities.

American Association of Blood Banks.—The first annual meeting of this organization will be held at the Hotel Statler, Buffalo, August 26-28, under the presidency of D. Albin Matson, Ph.D., Salt Lake City. Among the speakers will be: Harry Wallerstein, New York, Substitution Transfusion in Erythroblastosis Fetalis: Indications and Techniques; John D. Stewart, Buffalo, Blood Volume in Relation to Surgery; John Elliott, Sc.D., Miami, Fla., Red Cell Suspension Transfusions; Sidney C. Levinson, Chicago, Ultraviolet Irradiation of Plasma; Philip Levine, Newark, N. J., Routine Rh Tests for a Transfusion Service; Paul I. Hoxworth, Cincinnati, Blood Bank Organization, and Lloyd R. Newhouser, Washington, D. C., Blood Bank Procedures in Atomic Catastrophe.

International Congress on Industrial Medicine.—The Ninth International Congress on Industrial Medicine will be held in London, September 13-17, at the Caxton Hall, Westminster. Sections and the chairmen are as follows: social aspects, Professor Thomas Ferguson, Glasgow; environment, Professor Edward C. Dodds, London; nursing, Miss F. Clare Sykes, London; clinical, Professor Ronald E. Lane, Manchester; practice, Arthur J. Amor, London; special section, Dr. Edward R. A. Merewether, London. The official languages of the congress are French and English. The fee is 3 pounds (English money), payable to the treasurer, Dr. Margaret L. Dobbie-Bateman. Information may be obtained from Room 501, Garden Court Wing, B.M.A. House, Tavistock Square, London, W.C. 1.

Impostor.—Any one knowing the whereabouts of a person using the name of Samuel P. Hall and representing himself to be a physician should communicate with the prosecuting attorney at Manistique, Michigan. The person has been described as a white man, 30 years of age, 5 feet 11 inches tall, weighing about 160 pounds, with black hair, brown eyes and a small mustache, and as being a "classy dresser." He has apparently been posing as Samuel Pike Hall, who is a reputable physician at Oakland, Calif. He is not, of course, to be confused with Samuel Parks Hall Jr., of Scottsboro, Ala. Dr. Samuel Pike Hall recently advised us that he found the name of Samuel Pike Hall on a drug house mailing list. The address given in early 1948 was at a hospital in West Virginia, but the person using that name left after a short stay, without leaving a forwarding address.

Society Elections.—The American Urological Association, at its annual meeting May 19, installed Dr. Charles C. Higgins, Cleveland, president, and elected Dr. Carl F. Rusche, Los Angeles, president-elect. Dr. Thomas D. Moore, Memphis, Tenn., was reelected secretary and Dr. George C. Prather, Brookline, Mass., was reelected treasurer. The next annual meeting will be held at the Hotel Biltmore, Los Angeles, May 16-19, 1949.—At the annual meeting of the North Pacific Society of Neurology and Psychiatry held at Vancouver, B. C., April 2-3, Dr. Herman A. Dickel, Portland, Ore., was elected president; Dr. H. Ryle Lewis, Spokane, Wash., president-elect, and Dr. Gerhard B. Haugen, Portland, Ore., secretary-treasurer. The 1949 meeting of the society will be held in Portland, Ore.—The Association for Research in Nervous and Mental Diseases has elected Dr. Henry W. Woltman, Rochester, Minn., president.

Grants and Fellowships in Cancer Research.—The committee on growth of the National Research Council, acting for the American Cancer Society, will entertain applications for grants and fellowships. Applications for extension of existing grants in cancer research will be received until October 1, applications for new grants until November 1. Decision on applications submitted during this period will be made in most cases soon after February 1. Grants approved at this time ordinarily will become effective July 1, 1949. Fellowship applications may be submitted at any time. Those received prior to November 1 will be acted on by the Committee on Growth in December. Those received between November 1 and March 1 will be acted on in April. Fellowships ordinarily will begin July 1, though this date may be varied at the request of the applicant. During the past year the American Cancer Society, Inc., on recommendation of the Committee on Growth, has approved research grants and fellowships totaling over $2,000,000. Communications regarding grants and fellowships should be addressed to Executive Secretary, Committee on Growth, National Research Council, 2101 Constitution Avenue, N.W., Washington 25, D. C.

International Union Against Venereal Disease.—The General Assembly of the International Union Against Venereal Diseases will be held in Copenhagen, Denmark, September 6-10, at the invitation of the Danish Government and the Danish Society Against Venereal Disease. The agenda will include: (1) plans for the international venereal disease control program; (2) consideration of cooperation with the United Nations, the World Health Organization and UNESCO; (3) consideration of biologic, physiologic and psychologic aspects of human behavior in relation to control of venereal diseases; (4) treatment of syphilis; (5) the international inquiry concerning transmission of venereal diseases in the Rhine River district. The United States delegation to Copenhagen is expected to include, besides Dr. William F. Snow, Dr. and Mrs. Robert H. Bishop Jr., Cleveland; Major Louis N. Altshuler, M.C., U. S. Department of the Army, Dr. John R. Heller Jr., former venereal disease chief, U. S. Public Health Service, and Mrs. Josephine V. Tuller, assistant director of the union's regional office for the Americas. Information may be obtained from Miss Marguerite Troué, Administrative Secretary, at the international headquarters, Institut Fournier, 25, Boulevard Saint-Jacques, Paris XIV, France, or of Miss Jean B. Pinney, Director, Regional Office for the Americas, 1790 Broadway, New York 19.

National Board Elects New Members.—At the annual meeting of the National Board of Medical Examiners the following new members were elected: Dr. Russell L. Haden, Cleveland, who was nominated by the Council on Medical Education of the American Medical Association to succeed Major General Merritte W. Ireland, Washington, D. C.; Dr. Paul B. Magnusen, Chicago, medical director of the Veterans Administration; Dr. Eugene A. Gillis, Washington, D. C., who was nominated by Surgeon General Leonard A. Scheele, Washington, D. C., to succeed Major General Warren F. Draper, Washington, D. C., as a second representative from the U. S. Public Health Service; Dr. Winfred Overholser, superintendent of St. Elizabeth's Hospital and professor of psychiatry at George Washington University School of Medicine, Washington, D. C.; Dr. Hugh Rodman Leavell, Harvard University School of Public Health, and Dr. James V. Warren, professor of physiology, Emory University School of Medicine, Atlanta, Ga. The present officers were elected for another year as follows: Dr. Borden S. Veeder, St. Louis, president; Mr. Everett S. Elwood, executive secretary and treasurer, Philadelphia; and Dr. J. Stewart Rodman, Philadelphia, medical secretary. In addition to the officers the members of the executive committee for the ensuing year are: Dr. Roy B. Harrison, New Orleans, La.; Rear Admiral H. Lamont Pugh, Washington, D. C.; Dr. Robert W. Keeton, Chicago; and Dr. W. Barclay Parsons, New York. It is expected that the next annual meeting will be held at the time of the annual meeting of the American Medical Association at Atlantic City.

CANADA

Society News.—At the annual meeting of the Newfoundland Medical Association, St. Johns, Newfoundland, July 6-10, Dr. Robert J. Booher, assistant attending surgeon, Memorial Hospital for Cancer and Allied Diseases, and surgeon to the Pack Medical Group, spoke on "The Diagnosis and Surgical Management of Gastric Tumors" and "The Diagnosis and Management of Tumors of Soft Somatic Tissues."

Courses in Clinical Cytology.—McGill University Faculty of Medicine, Montreal, will present two courses in the diagnosis of uterine cancer this fall. One, from September 6 to October 5, is for physicians interested in cytologic technics, staining methods and interpretation. September 6-10, another course of general lecturers and demonstrations will take up the practical application of the vaginal smear and the "surface-biopsy" to every day practice. Tuition for the last course will be $25.

PUERTO RICO

Puerto Rico Medical Association Meeting.—At a special meeting of the Puerto Rico Medical Association in Ponce, July 23-25, Dr. Harry Gold, professor of clinical pharmacology, Cornell University Medical College, New York, delivered several lectures. A round table discussion on tuberculosis was held under the direction of Dr. Juan A. Pons, San Juan, commissioner of health of Puerto Rico. On July 25 a memorial plaque in honor of the late Dr. Bailey K. Ashford was unveiled on the same building in Ponce where this U. S Army medical officer determined the cause (hookworm) of anemia of the agricultural class of Puerto Rico in 1899.

Public Health Meeting.—The Puerto Rico Public Health Association elected the following board of directors for 1948 at its annual meeting held in San Juan: Drs. Juan A. Pons, president; Americo Pomales, vice-president, and Nelson Biaggi, secretary. The association recommended the creation of a mental hygiene bureau in the Insular Department of Health. The papers read at this meeting will be integrated in a single document to be presented before the Mental Hygiene Congress next August at London, England. Records were taken of the most important Spanish lectures, which are to be reproduced in Latin American countries. Among the American doctors who were guests of honor were Charles E. A. Winslow, Dr. P.H., New Haven, Conn.; William W. Peter, of the Inter-American Affairs Institute, Washington, D. C.; Harold W. Brown, Columbia University, New York; Robert S. Freed, New York Agricultural Experiment Station; E. J. Herringer, sanitary engineer, U. S. Public Health Service, and Reginald M. Atwater, Dr. P.H., executive secretary, American Public Health Association.

CORRECTIONS

Cesarean Hysterectomy.—In the paper on this subject in THE JOURNAL, July 17, page 1017, bibliographic reference no. 3 at the bottom of the page should read as follows: Baldwin, J. F.: Tr. Am. A. Obs., Gynecol. and Abd. Surgeons **42:**98, 1929.

Roentgenologic Treatment of Lymph Nodes and Spleen.—In the article by Dr. Sidney Rubenfeld in THE JOURNAL, July 3, 1948 "(fig. 2)," should be deleted from line eight in the second column on page 849. In the legend of figure 4, the second word in the second line should be "identified." On page 850, line 2 "(figs. 3 and 4)," should be "(figs. 2 and 3)." On page 850, column one, lines six and seven, "fig. 4" should be added to "(figs. 5, 6 and 7)."

Deaths

Robert Bruce Preble ⊕ Chicago, professor of medicine at Northwestern University Medical School, died at St. Luke's Hospital July 26, aged 82, of myocardial infarction, diabetes mellitus and third degree burns. Dr. Preble was born in Chicago, March 14, 1866. He was graduated from the University of Michigan in Ann Arbor in 1889 and received his medical degree from Northwestern University Medical School, Chicago, in 1891. Later he interned at the Cook County Hospital, where he served on the staff, and in 1894 studied at the University of Vienna. The following year he joined Northwestern as professor of medicine. Dr. Preble was secretary of the Section on Practice of Medicine of the American Medical Association in 1901-1902, and was past president of the Chicago Medical Society and the Chicago Heart Association. He was a member of the Association of American Physicians and a specialist certified by the American Board of Internal Medicine. In April 1917 he was commissioned a major in the medical reserve corps; he served as chief of the hospital center at Mars Sur Alliers, France, and on Jan. 31, 1919, was discharged with the rank of lieutenant colonel. Dr. Preble received an American citation and the French Legion of Honor. He was attending physician at St. Luke's and Wesley Memorial hospitals, and was the author of a book on "*Pneumonia and Pneumococcus Infections*" written in 1905.

Edward Speidel, Louisville, Ky.; born in Philadelphia, Nov. 12, 1859; University of Louisville Medical Department, 1895; also a graduate in pharmacy; professor emeritus of obstetrics at his alma mater; specialist certified by the American Board of Obstetrics and Gynecology, Inc.; past president of the Jefferson County Medical Society and the Louisville Society of Obstetricians; member of the American Association of Obstetricians, Gynecologists and Abdominal Surgeons and the American Medical Association; fellow of the American College of Surgeons; served on the staffs of the City, Jewish, St. Anthony's and Kentucky Baptist hospitals and the Norton Memorial Infirmary; died April 13, aged 88.

Murray Nathan Fowler, Mansfield, Ohio; University of Toronto Faculty of Medicine, Toronto, Ont., Canada, 1923; member of the American Medical Association and of the American Psychiatric Association; during World War II served as chief psychiatrist for the disciplinary training center of the Mediterranean theater of operations and was discharged with rank of major; formerly on the staff of the Athens (Ohio) State Hospital and superintendent of the Institution for Feeble-Minded at Apple Creek; psychiatrist at the Ohio State Reformatory; died in the Mansfield General Hospital April 29, aged 49.

Carmelo Baldini, New York; Regia Università di Napoli Facoltà di Medicina e Chirurgia, Italy, 1912; member of the American Medical Association; major in the medical corps of the Italian Army during World War I; died March 2, aged 61, of carcinoma, following roentgen ray burns.

Edward Hagop Bedrossian ⊕ Philadelphia; University of Pennsylvania School of Medicine, Philadelphia, 1912; Army School of Aviation Medicine, San Antonio, Texas, in 1927; lieutenant colonel, air force reserve flight surgeon; formerly demonstrator in ophthalmology at the Temple University School of Medicine; chief of department in ophthalmology at Delaware County Hospital in Drexel Hill, Pa.; died in Clifton Forge, Va., April 17, aged 61, of coronary thrombosis.

David P. Bowman, Crimora, Va.; University of Pennsylvania Department of Medicine, Philadelphia, 1887; died in the King's Daughters' Hospital, Staunton, April 14, aged 90.

Lawrence Bernard Boylan, Paterson, N. J.; Maryland Medical College, Baltimore, 1913, member of the American Medical Association; formerly supervisor of school hygiene and county physician; city physician; served during World War I; affiliated with St. Joseph's and Paterson General hospitals; died April 14, aged 59, of chronic myocarditis.

Bernard Eugene Britt, Nashville, Tenn.; University of Nashville Medical Department, 1905; died April 29, aged 72.

Anna Frances S. Lee Brown, Denver; the Hahnemann Medical College and Hospital, Chicago, 1893; at one time health officer of Telluride, Colo.; died April 8, aged 80, of pneumonia.

Leo Greenleaf Bruce, Durham, N. C.; Meharry Medical College, Nashville, Tenn., 1926; member of the board of directors of the Durham County Tuberculosis Association and of the Durham Chapter of the American Cancer Society; affiliated with the Lincoln Hospital; died April 7, aged 49, of carcinoma of the lung.

Robert Finley Campbell, Phoenix, Ariz.; University of Kansas School of Medicine, Kansas City, 1921; died April 19, aged 54, of perinephritic abscess.

Frederick S. Casto, Charleston, W. Va.; University of Louisville (Ky.) Medical Department, 1893; formerly justice of the peace in Kenna and for many years president of the board of pension examiners of Jackson County; died April 19, aged 81, of heart disease.

Ernest Johnson Colberg, Alameda, Calif.; University of Minnesota Medical School, Minneapolis, 1924; died April 17, aged 60.

William Gregory Cole ⊕ Pittsfield, Mass.; Columbia University College of Physicians and Surgeons, New York, 1928; specialist certified by the American Board of Radiology, Inc.; member of the Radiological Society of North America, Inc.; on the staffs of the House of Mercy and Hillcrest hospitals in Pittsfield and Fairview Hospital in Great Barrington; formerly on the staff of St. Agnes Hospital in White Plains, N. Y.; died in Bermuda April 15, aged 46, of coronary thrombosis.

Charles Chapman Collester ⊕ Spencer, Iowa; Jefferson Medical College of Philadelphia, 1909; fellow of the American College of Surgeons; affiliated with the Spencer Municipal Hospital; died April 11, aged 62, of carcinoma of the prostate.

Donald Grey Colp, Robbinsdale, Minn.; Minneapolis College of Physicians and Surgeons, 1908; at one time a minister; died in Northwestern Hospital, Minneapolis, April 14, aged 78, of carcinoma of the lung with general metastases.

Augustus Eugene Conter, Apalachicola, Fla.; Atlanta College of Physicians and Surgeons, 1902; member of the American Medical Association; veteran of the Spanish-American War; at one time secretary-treasurer of the Jefferson County Medical Society; died April 12, aged 76, of coronary occlusion.

Howard L. Corbus, Harrisburg, Pa.; Western Pennsylvania Medical College, Pittsburgh, 1892; served on the staff of the Harrisburg State Hospital; died April 6, aged 79, of coronary thrombosis.

Walter Louis Cottingham ⊕ Seattle; the Hahnemann Medical College and Hospital, Chicago, 1913; served as president of the Ford County (Ill.) Medical Society; on the staff of the Columbus Hospital; died April 14, aged 66, of angina pectoris.

William Thomas Cox, Gentry, Ark. (licensed in Arkansas in 1903); died April 3, aged 81, of acute dilatation of the heart.

Carl J. Cramm ⊕ Russell, Kan.; University of Louisville (Ky.) Medical Department, 1897; for many years county health officer; president of the staff of Russell City Hospital; died in Ellsworth (Kan.) Hospital April 14, aged 72, of carcinoma of the rectum.

Charles Balfour Darling, Waban, Mass.; Harvard Medical School, Boston, 1894; member of the American Medical Association; for many years on the faculty of Tufts College Medical School, Boston; served during World War I; charter member of the staff of the Free Hospital for Women in Jamaica Plain; died in the New England Baptist Hospital, Boston, April 19, aged 78, of duodenal ulcer.

David J. Evans ⊕ Bethesda, Md.; Rush Medical College, Chicago, 1898; member of the Illinois State Medical Society; fellow of the American College of Surgeons; for many years practiced in Aurora, Ill., where he served on the staffs of the St. Joseph Mercy, St. Charles and Copley hospitals; died in the Suburban Hospital April 7, aged 75, of coronary thrombosis.

John Henry Fager Jr. ⊕ Harrisburg, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1904; past president of the Harrisburg Academy of Medicine; affiliated with the Harrisburg Hospital; died April 14, aged 70, of cerebral thrombosis.

Charles Wood Fassett, Burlingame, Calif.; Ensworth Medical College, St. Joseph, Mo., 1900; member of the American Medical Association; member and past president of the Missouri State Medical Association; served as secretary of the Buchanan County (Mo.) Medical Society and of the Missouri Valley Medical Society; died April 14, aged 86.

Charles W. Gardiner, Batavia, N. Y.; University of Vermont College of Medicine, Burlington, 1891; died April 30, aged 82, of coronary sclerosis.

George Franklin Garland, Winthrop, Mass.; Baltimore Medical College, 1898; died March 28, aged 81, of chronic myocarditis.

Clara Hyde Gillard, Cleveland; the Hahnemann Medical College and Hospital, Chicago, 1889; died in Port Clinton April 8, aged 86, of acute myocardial failure.

William George Gordon ⊕ Birmingham, Mich.; University of Michigan Medical School, Ann Arbor, 1935; member of the Kansas State Medical Society; fellow of the American College of Surgeons; served an internship and residency at the University Hospital in Ann Arbor; formerly associate professor of surgery at the University of Kansas School of Medicine, Kansas City, Kan.; died April 21, aged 36, of asphyxia.

James Allen Green ⊕ Clayton, Ga.; Atlanta College of Physicians and Surgeons, 1908; served as mayor and councilman of Clayton; for many years a trustee of the local school; died in the Emory Hospital, Atlanta, March 23, aged 65, of hypertensive cardiovascular disease.

William Edwin Herring, Ida, La.; College of Physicians and Surgeons, Baltimore, 1891; died April 19, aged 86.

Stanley Vincent Hodge ⊕ Minneapolis; Northwestern University Medical School, Chicago, 1910; served during World War I; died in the Swedish Hospital April 27, aged 67, of acute cardiac failure.

Jennie Hraba, Boston; Middlesex College of Medicine and Surgery, Cambridge, Mass., 1921; died March 5, aged 71, of cerebral hemorrhage.

Allan Pettit Hughes, Auburn, Wash.; the Hahnemann Medical College and Hospital, Chicago, 1907; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1909; member of the American Medical Association; served during World War I; died in Auburn General Hospital April 3, aged 67, of complications following a cerebral hemorrhage.

William Jennings Irby, Benton, Kan.; Kansas City (Mo.) College of Medicine and Surgery, 1917; member of the American Medical Association; president of the Butler County Medical Society; served during World War I; affiliated with the Allen Memorial Hospital, El Dorado, Bethel Hospital, Newton, Wichita Hospital, St. Joseph's Hospital, St. Francis Hospital and Wesley Hospital in Wichita and the Bell Memorial Hospital in Kansas City; died near Strong City, April 8, aged 55, of injuries received in an automobile accident.

Fred Anderson Jones, Paducah, Ky.; Vanderbilt University School of Medicine, Nashville, 1914; member of the American Medical Association; past president of the McCracken County Medical Society; on the staffs of Riverside Hospital and Illinois Central Hospital, where he died April 16, aged 68, of cirrhosis of the liver and carcinoma of the sigmoid.

Joseph Adelard Laurion, Somerville, Mass.; Albany (N. Y.) Medical College, 1895; died March 20, aged 77, of myocardial failure.

Lester Benjamin Lougee, Marilla, N. Y.; Physio-Medical College of Indiana, Indianapolis, 1896; member of the American Medical Association; served as health officer; founder and president of the Marilla Library; on the staff of the Deaconess Hospital in Buffalo, where he died April 11, aged 76, of heart disease, following an operation.

James Straine Louthan, Beaver Falls, Pa.; Western Reserve University Medical Department, Cleveland, 1882; member of the American Medical Association; physician for the Pittsburgh and Lake Erie Railroad; died April 12, aged 93.

Joseph Wooding Love, Springfield, Mo.; College of Physicians and Surgeons, medical department of Columbia College, New York, 1890; member of the American Medical Association; past president of the Missouri State Medical Society; for many years secretary and past president of the Greene County Medical Society; past president of the Southwest Clinical Society; died in the Veterans Administration Hospital, Little Rock, May 3, aged 81, of bronchopneumonia and cerebral arteriosclerosis.

Norris C. Magraw, Cadiz, Ky.; University of Louisville Medical Department, 1894; member of the American Medical Association; died in the Jennie Stuart Hospital in Hopkinsville, April 19, aged 75, of complications as the result of a fractured hip received in a fall on an icy pavement in February.

Paul John Mateicka, Milwaukee; University of Wisconsin Medical School, Madison, 1942; member of the American Medical Association; interned at the Indiana University Medical Center in Indianapolis; on the staff of the Sacred Heart Sanitarium and an instructor at the school of nursing; died April 13, aged 32.

Daniel Bradford McCann, Los Angeles; Rush Medical College, Chicago, 1890; died April 10, aged 89, of myocarditis.

William Emmett McClain, Seattle; Keokuk (Ia.) Medical College, College of Physicians and Surgeons, 1905; member of the American Medical Association; on the staffs of the Ballard General and Columbus hospitals; died April 10, aged 70, of coronary occlusion.

Charles Ellsworth McCune ⊕ West Springfield, Pa.; Western Pennsylvania Medical College, Pittsburgh, 1897; died in Erie April 7, aged 85, of pulmonary tuberculosis.

William Henry McKinney, Athena, Ore.; Gate City Medical College, Dallas, 1908; Eclectic Medical University, Kansas City, 1917; died in Pendleton March 2, aged 65.

Aaron Moore ⊕ Central Islip, N. Y.; Tulane University of Louisiana School of Medicine, New Orleans, 1924; member of the American Psychiatric Association; served on the staff of the Central Islip State Hospital; died April 3, aged 49, of coronary occlusion.

David Cowee Pierpont ⊕ Ironwood, Mich.; Columbia University College of Physicians and Surgeons, New York, 1903; on the staff of the Newport Hospital; died April 15, aged 69, of coronary occlusion.

Clyde E. Purcell ⊕ Paducah, Ky.; Hospital College of Medicine, Louisville, 1903; died in the Riverside Hospital April 23, aged 75, of cerebral hemorrhage.

Charles Duncan Rankin, Flippin, Ark.; St. Louis College of Physicians and Surgeons, 1922; Kansas City (Mo.) College of Medicine and Surgery, 1923; died in Gassville April 30, aged 72, of heart disease.

Ida Virginia Reel, Philadelphia; Woman's Medical College of Pennsylvania, Philadelphia, 1882; died April 28, aged 91, of coronary thrombosis.

Franklin Ward Renfrew, Goshen, Conn.; Cornell University *Medical College, New York, 1919; member of the* American Medical Association; served during World War I; during World War II was connected with the U. S. Public Health Service; formerly on the staffs of the Beekman-Downtown and City hospitals in New York; died April 29, aged 55, of cerebral hemorrhage.

Francis M. Reynolds, *Montpelier, Ind.; Medical College* of Indiana, Indianapolis, 1897; served as mayor; died April 16, aged 78, of coronary disease.

Schuyler Parshall Richmond, Syracuse, N. Y.; Syracuse University College of Medicine, 1903; member of the American Medical Association; associate clinical professor of medicine and dermatology at his alma mater; affiliated with the Memorial, University and St. Joseph's hospitals; died April 8, aged 67, of transverse myelitis.

Harvey Hamilton Roberts ⊕ Georgetown, Ky.; Medical College of Ohio, Cincinnati, 1890; past president of the Scott County Medical Society; served on the staff of the Good Samaritan Hospital, Lexington; died in St. Joseph's Hospital, Lexington, April 19, aged 82, of coronary heart disease.

Maurice Rosier, St. Petersburg, Fla.; University of the South Medical Department, Sewanee, Tenn., 1899; served in the U. S. Navy during World War I; died April 30, aged 73.

Philip Edward Rossiter, Avon, N. Y.; Long Island College Hospital, Brooklyn, 1902; member of the American Medical Association; served during World War I; later an officer in the regular army; formerly affiliated with the U. S. Veterans Bureau; died in the Strong Memorial Hospital, Rochester, April 30, aged 71, of bronchopneumonia.

Frederick Schwartz, Philadelphia; Jefferson Medical College of Philadelphia, 1888; died in Sea Isle City, N. J., April 19, aged 85, of carcinoma of the pancreas.

Cornelius James Seay, Scarsdale, N. Y.; University College of Medicine, Richmond, 1898; member of the American Medical Association and the American Urological Association; died in White Plains (N. Y.) Hospital April 24, aged 74, of carcinoma.

Edmund Spicer, Waterbury, Conn.; Yale University School of Medicine, New Haven, 1905; member of the American Medical Association; fellow of the American College of Surgeons; for many years on the staff of the Waterbury Hospital; died April 12, aged 66, of ruptured aneurysm of the aorta.

Joseph Blankinship Thigpen, Bay Springs, Miss.; Medical Department of Tulane University of Louisiana, New Orleans, 1905; member of the American Medical Association; served as county health officer; president of the Bay Springs Bank; died April 27, aged 66, of tuberculosis.

Charles Sherman Van Ness, Peterson, Iowa; Queen's University Faculty of Medicine, Kingston, Ont., Canada, 1904; died April 26, aged 74, of cerebral hemorrhage.

William H. Winningham, Trenton, Mo.; Marion-Sims College of Medicine, St. Louis, 1893; member of the American Medical Association; on the staff of the Wright Memorial Hospital, where he died April 30, aged 80, of myocarditis.

Beverly Thomas Young, Glennville, Calif.; University of Texas School of Medicine, Galveston, 1907; died in a hospital at Bakersfield April 8, aged 64.

Annual Meeting of British Medical Association

The first normal postwar annual meeting of the British Medical Association was held at Cambridge and was well attended, in spite of the difficulties of travel by car, food rationing, shortage of accommodation and other obstacles arising from the abnormal condition of the country which still persists after the war. At the meeting of representatives it was announced that the previous week 65,000 copies of the *British Medical Journal* had been posted, which was a record, and over 3,000,000 copies had been printed in the last year. The increase in circulation was partly due to increased membership of the association and also to increased subscriptions from nonmembers. From the business point of view, last year was extremely profitable. The excess of receipts over expenditure amounted to $124,000. A new quarterly, the *Journal of Clinical Pathology*, had been added to the publications of the association. The two abstracting journals, the *Abstract of World Medicine* and the *Abstract of World Surgery*, had been well received, and the circulation had reached the estimated figure by the end of the first year of publication. The total income of the association was $676,000.

Waste of Physician's Time Under Medical Socialism

In their enthusiasm for medical socialism its advocates entirely overlook its drawbacks. In a letter to the *Times* a physician who has had much experience of it in the panel system shows how much time is wasted. At least one third of his panel patients come for no medical purpose at all. They come for certificates of a great variety or for the repeat of a prescription. Here lies the main difference between panel and private practice and the main reason for so much unnecessary work which clutters up the office and prevents good work for those needing a physician's care. The private patient, having seen his doctor, can get his prescription repeated as often as necessary by simply going to the pharmacist, but the panel prescription can be dispensed only once. For every fresh bottle the panel patient must visit the physician to obtain a fresh prescription, wasting his own time and the physician's time. It may be asked: "Why not make a new regulation abolishing the difference?" The answer reveals another drawback of medical socialism. The panel patient gets his medicine free, and, with the universal craving for bottles of medicine of the hypochondriacs of the English masses, the waste which exists under the panel system would be multiplied. This point entirely escaped the Minister of Health when he claimed that when the cash relationship between doctor and patients disappeared the doctors would devote their time to patients who really needed them, instead of to wealthy hypochondriacs. What his service will do is to render general, because free, indulgence in hypochondria.

Gerontologic Conference

A conference of the British Society for Research on Aging will be held at the Royal Society of Medicine, London, on July 7 from 10 a. m. to 6:30 p. m. Papers on the result of their gerontologic researches will be read by Sir Frederick Bartlett, F. R. S., Prof. E. C. Dodds, F. R. S., F. Bourliere (Paris), L. Cosin, F. A. Denz, E. Geiringer, V. Korenchevsky, O. Olbrich, H. Brown and M. H. Ferguson, and Professor Beltran-Baguena (Valencia University).

British Surgeon Visits Australia

Early this year the first Sims Commonwealth Professor of the Royal College of Surgeons, Sir Hugh Cairns, visited Australia and New Zealand, where he delivered many lectures, conducted clinics and attended conferences. He has presented a report to the College. Perhaps the most important result is his suggestion that the time has come to found medical fellowships for graduates in Britain to do postgraduate work in Australia and New Zealand, where there are experts well known all over the world. It is hoped that in time medical teachers and research workers will be freely exchanged between all parts of the Commonwealth.

ITALY

(*From Our Regular Correspondent*)

Florence, June 19, 1948.

Surgical Treatment of Pulmonary Tuberculosis

At the National Congress, the Italian Surgical Association gave extensive consideration to the surgical treatment of pulmonary tuberculosis. The first speaker, Prof. N. Di Paola, discussed intrapleural pneumonolysis and surgical intervention on the phrenic nerve. The cutting of adhesions, or pneumonolysis, is clinically important because their presence favors recurrence of the lesions which were stabilized after treatment by pneumothorax; its performance seems advisable also in those cases in which pneumothorax is ineffective. Depending on the type of adhesion (simple or complex), the indications may be those of necessity, of urgency or of security; it is the author's definite concept that all types of adhesions should be cut. He stated that the pressure of the pneumothorax should be graduated so that the adhesions appear well delineated before the intervention. The instrument should be one with a handle and independent optics. The postoperative management is of great importance for the Jacobaeus operation. Failures and complications may be caused by defects of technic and by incongruous pneumothoracic treatment in the immediate postoperative period. Among 1,460 cases in which the operation was performed, 84 per cent were without any complication; in 13 per cent there occurred a temporary circumscribed pleurisy; chronic tuberculous empyema occurred in about 1 per cent, and emphysema was manifested in 0.6 per cent.

In discussing surgical intervention on the phrenic nerve, the speaker demonstrated that the results correspond to the topography and to the anatomicopathologic type of the lesions. For apical lesions it is wrong to depend on the autonomous phrenicoexeresis; it is much better to perform at once a thoracoplasty or an extrapleural pneumothorax. On the contrary, the parahilar lesions present a good indication. The basal lesions do not constitute any indication of choice. Some satisfactory results have been obtained by combining phrenicoexeresis with unilateral pneumothorax and phrenicoexeresis with pneumoperitoneum. The speaker condemned the prethoracoplastic phrenicoexeresis and considered it favorable to cut the phrenic nerve after the thoracoplasty in cases of apicocaudal bronchopneumonic aspiration. He was not enthusiastic about phrenicoexeresis as a satisfactory treatment by itself. He considered it safe to assume that in a few, well determined circumstances, a small number of permanent good results may be obtained by surgical intervention on the phrenic nerve.

Professor Biancalana discussed scaleniotomy, pneumonolysis and surgical extrapleural pneumothorax. Scaleniotomy has been abandoned as a surgical treatment by itself, but represents one stage of upper thoracoplasty. Pneumonolysis with plumbage has been abandoned completely since the advent of modern thoracoplasty; only pneumonolysis combined with the filling of collapsed lung cavities with paraffin has survived, and this finds its indications in persons of a certain age and as a preparatory treatment for thoracoplasty in patients with large cavities with considerable secretion, or as a supplementary treatment to thoracoplasty in patients with residual cavities. The combination of apicolysis with thoracoplasty may be employed to obtain better release of the apex of the lungs and, consequently, a much higher percentage of closure of cavities.

In surgical extrapleural pneumothorax the extensive detachment of the parietal pleura provokes collapse of the lung, which may be maintained by supplying more air. The intervention is fairly easy and well tolerated by the patients, but at first many failures and complications occurred The results were improved by perfecting the operative technic and postoperative management and by a better selection of cases. One characteristic of the intervention is the reversibility of the collapse; reexpansion of the lung may be obtained after three or more years when the extrapleural pneumothorax is discontinued.

Professor Ruggieri reported on thoracoplasty, lobectomy and pneumonectomy. The principal types of thoracoplasty are simple partial upper thoracoplasty; partial upper thoracoplasty with complementary apicolysis, total and subtotal thoracoplasty and anterolateral thoracoplasty according to Monaldi. In criticizing each type of intervention, the speaker said that there is no standard operation which may be adopted independently of the infinite variety of tuberculous lesions; on the contrary, the intervention must be adapted to the morbid process in each case. In deciding to do a lobectomy or pneumonectomy it is absolutely necessary to use much caution; however, these procedures should have a definite place in the surgical therapy of pulmonary tuberculosis, since their usefulness is beyond doubt in some forms of the disease.

The last report on the subject was presented by Professor Omodei Zorini of the University of Rome. His personal experience gives evidence of the possibility of total reexpansion of the lung after the extrapleural pneumothorax has been discontinued, and of the usefulness of combining it with treatment with penicillin and streptomycin, to avoid suppurative complications. The extrapleural pneumothorax may be considered a satisfactory accomplishment by modern phthisiology.

The speaker is opposed to thoracoplasty even if the pleura is left untouched. He considers preventive phrenicoexeresis as harmful in many cases of upper cavities and of bilateral lesions, in which it is necessary to spare the function of the diaphragm.

With Bottari and Di Paola, Professor Zorini presented 7 cases of large cavities with much secretion, in which recovery was obtained from treatment by collapse of the lobe. This method suggested by Bottari consists of the combined endocavitary aspiration and administration of streptomycin into the cavity and also parenterally before and after an apicoaxillary and posterior thoracoplasty. By this procedure one may be successful in obtaining a rapid and complete collapse of the entire diseased lobe of the lung.

OSLO

Health Passports

It would be helpful for all concerned if everyone had a written health record to show the last physician consulted. In 1946, Dr. Evang, head of the Norwegian Public Health Service, appointed a committee to inquire into the problem of health passports. A year later this committee issued its recommendations. At the school-leaving age, but not earlier, everyone should be supplied with a booklet in which every fact of major importance concerning the owner's health should be entered. Finding that the health passports already in tentative use in Norway do not satisfy requirements, the committee drafted a 16 page health passport of its own.

A copy of this booklet has been issued with every number of the *Journal of the Norwegian Medical Association* for May 1, 1948. In the same issue Dr. Evang gives a brief account of health passports in general. He concludes: "Before the plan of introducing health passports is promoted, it would be desirable to have comments on the present draft from as many as possible of the country's doctors." In subsequent issues of the same journal several physicians have taken Dr. Evang at his word and aired their not always favorable opinion of his infant. As was to be expected, the chief stumbling block concerns the diseases one prefers to keep to himself, notably the venereal diseases. But there are other diseases, such as tuberculosis, the presence of which one does not wish to publish from the housetops. Yet the advantages of a health passport are so great that it is hoped that Dr. Evang will succeed, so that even the most captious critic will hail it as an essential feature of the campaign for better health.

The Costly and Wasteful M.D. Degree

Few physicians in Norway are entitled to the degree of Doctor of Medicine. This is so because one must be endowed with ample means, brains, ambition, leisure, vitality and other more or less essential equipment for the long march which may or may not ultimately give one the much coveted degree. Is it worth while? If it is, ought not something radical be done to improve this institution? To be sure, a special committee is at present engaged on the "reform of the M.D.," but it is not known when its recommendations will be published.

The faults of the present system were recently exposed with blunt candor by Dr. Thjøtta, Professor of Bacteriology at the University of Oslo, on the occasion of a graduation ceremony for the M.D. degree. These were his points: The printing alone of an M.D. thesis recently cost its author Kr. 16,000 (over $3,000). M.D. theses are apt to be stuffed with quotations dragged in to demonstrate the author's erudition. The valuable time of the experts who have to pass judgment on one such *magnum opus* after another every year is frittered away, and their own research work is handicapped. As Professor Thjøtta remarked: "Everyone will see that one cannot expect much scientific work from the Norwegian Professors of Medicine in these circumstances."

But what was, perhaps, Professor Thjøtta's most important point was that the present system for attaining the M.D. degree is a real check on scientific team work in Norway. For the prospective Doctor of Medicine must work out a problem all by himself, although it would have been much better dealt with by a team composed of, say, a pathologist, a clinician, a bacteriologist and others. The one horse show is today an anachronism.

Prevention of Tuberculosis in the Fighting Services

On paper at any rate, the machinary for keeping tuberculosis out of the Norwegian fighting services is almost fool proof. Every new recruit is subjected to a searching medical examination, including tuberculin tests and a radiologic examination of the lungs. At intervals of three months, the radiologic examination is repeated and negative reactors to tuberculin are tested anew. When, in spite of these precautions, a member of the fighting services is found to be tuberculous, all who have recently been in contact with him are examined. Recruits found to have negative reactions to tuberculin are recommended for BCG vaccination which, voluntary in the past, can now be enforced.

Professor Axel Ström, who is the highest authority on the subject in Norway and largely responsible for the health of the fighting services, has given an account of an outbreak of tuberculosis in the Norwegian navy. A recruit suffering from cavernous pulmonary tuberculosis and with tubercle bacilli in his sputum was not recognized as having tuberculosis until he had infected several of his companions, 65 of whom reacted in some way or other to the infection. Twenty-five of them merely became tuberculin-positive; another 25 became tuberculin-positive and also presented hilar adenitis. In 3 erythema nodosum developed; pleurisy developed in 5, pulmonary infiltration in 6 and pulmonary infiltration with cavity formation in 1. Professor Ström refers to many other similar incidents, some of which also assumed epidemic proportions. The weakest link in the chain is the fact that the tuberculin-negative recruit who is vaccinated with BCG on joining does not become allergic to tuberculin until several weeks later, and in the meantime he may contract tuberculosis. The remedy Professor Ström proposes in this connection is the tuberculin test and BCG vaccination of negative reactors before they are called up. Now that BCG vaccination is compulsory in Norway, it ought to be possible to give effect to this proposal.

Council on Medical Education and Hospitals

AMENDED INTERN PLACEMENT PLAN

Paragraphs three and four of the Uniform Intern Placement Plan, as published in The Journal, March 6, 1948, have been amended for clarification by the joint action of the Council on Medical Education and Hospitals of the American Medical Association, the Association of American Medical Colleges, the American Hospital Association, the Protestant Hospital Association and the Catholic Hospital Association. The following is the full text of the amended plan:

PLAN FOR THE YEAR 1948-1949 FOR INTERNSHIPS BEGINNING JULY 1, 1949

1. Applications and credentials to be submitted only through the dean's office to hospitals, with the date for filing applications and release of credentials by the medical schools set at Oct. 15, 1948. Credentials ordinarily will consist of an executed application blank and a letter from the dean but do not preclude such letters from members of the faculty as they may wish to write, unsolicited by the candidate.
2. Applicants may visit hospitals and be interviewed by hospital intern committees, but the hospital administration shall not commit the hospital or obligate the applicant, or potential applicants, before Nov. 15, 1948.
3. No intern appointments shall be tendered prior to Nov. 15, 1948 to applicants who are members of the senior class in medical schools. Notice by telegram is preferable. Hospitals may decline an applicant at any time.
4. Applicants shall send acceptances or rejections of appointments so that they are received at the hospital by midnight of Nov. 18, 1948; but commitments by applicants shall not be required prior to that time.
5. These regulations shall apply only to undergraduate medical students who have not completed the fourth year of their medical course.

The previous wording of the amended paragraphs was as follows:

3. No intern appointments shall be made prior to Nov. 15, 1948, from applicants who are members of the senior class in medical school. Hospitals may decline an applicant at any time.
4. Applicants shall accept or reject hospital appointments before midnight of Nov. 18, 1948.

Medical Examinations and Licensure

COMING EXAMINATIONS AND MEETINGS

EXAMINING BOARDS IN SPECIALTIES

American Board of Anesthesiology: *Written.* Various Centers, Jan. 21, 1949. Final date for filing application is Oct. 1. *Oral,* Philadelphia, Oct. 10. Sec., Dr. Paul M. Wood, 745 Fifth Ave., New York 22.

American Board of Internal Medicine: *Written.* Oct. 18. Asst. Sec., Dr. W. A. Werrell, 1 W. Main St., Madison 3, Wis.

American Board of Neurological Surgery: *Oral.* Chicago, June 1949. Final date for filing application is Jan. 1949. Sec., Dr. W. J. German, 310 Cedar Street, New Haven, Conn.

American Board of Obstetrics and Gynecology: *Part I.* Various Centers, Feb. 4, 1949. Final date for filing application is Nov. 1. Sec., Dr. Paul Titus, 1015 Highland Bldg., Pittsburgh 1.

American Board of Ophthalmology: *Oral.* Chicago, Oct. 6. *Written.* Various Centers, January 1949. Sec., Dr. S. J. Beach, 56 Ivie Rd., Cape Cottage, Maine.

American Board of Orthopedic Surgery: *Part II.* Chicago, January 1949. Final date for filing application is August 15. Sec., Dr. Francis M. McKeever, 1136 W. 6th St., Los Angeles 14.

American Board of Otolaryngology: *Oral.* Chicago, Oct. 5-8. New York City, Spring, 1949. Sec., Dr. D. M. Lierle, University Hospital, Iowa City.

American Board of Pathology: Chicago, Oct. 8-9. Final date for filing application is Oct. 1. Sec., Dr. Robert A. Moore, 507 Euclid Ave., St. Louis.

American Board of Pediatrics: *Oral.* Seattle, Sept. 10-12. Atlantic City, Nov. 17-19. Sec., Dr. Lee F. Hill, 718 Royal Union Bldg., Des Moines, Iowa.

American Board of Plastic Surgery: Examinations are given in June and November of each year in the hometown of applicants. Sec.-Treas., Dr. Louis T. Byars, 400 Metropolitan Bldg., St. Louis, Mo.

American Board of Radiology: Nov. Final date for filing application is Sept. 1. Sec., Dr. B. R. Kirklin, 102-110 Second Ave., S.W. Rochester, Minn.

American Board of Surgery: *Written.* Various Centers, March 1949. Final date for filing application is Dec. 1. Sec., Dr. J. S. Rodman 225 S. 15th St., Philadelphia.

American Board of Urology: Chicago, Feb. 12-16, 1949. Final date for filing application is Sept. 1. Sec., Dr. Harry Culver, Route #13, Sunnyside Rd., Minneapolis 4.

BOARDS OF MEDICAL EXAMINERS

Alabama: *Examination.* Montgomery, June 28-30, 1949. Sec., Dr. D. G. Gill, 519 Dexter Ave., Montgomery.

Alaska: * *Examination.* Juneau, Sept. 7. Sec., Dr. W. M. Whitehead, Box 140, Juneau.

Arkansas: *Eclectic Examination.* Little Rock, Nov. 4. Sec., Dr. C. H. Young, 1415 Main St., Little Rock.

California: *Oral.* Los Angeles, Nov. 20-21. *Written.* Sacramento, Oct. 18-21. Sec., Dr. Frederick N. Scatena, 1020 N Street, Sacramento 14.

Connecticut: * *Examination.* Hartford, Nov. 9-10. Sec., Dr. Creighton Barker, 258 Church St., New Haven.

District of Columbia: * *Reciprocity.* Washington, Sept. 13. Sec., Commission on Licensure, Dr. G. C. Ruhland, 4130 Municipal Bldg., Washington, D. C.

Georgia: *Examination.* Atlanta, Oct. 12-13. *Endorsement.* Atlanta, Oct. 14. Sec., Mr. R. C. Coleman, 111 State Capitol, Atlanta.

Illinois: Chicago, Oct. 5-7. Supt., Dept. of Registration and Education, Mr. Fred W. Ruegg, Capitol Bldg., Springfield.

Indiana: *Examination.* Indianapolis, June 1949. Sec., Board of Medical Registration & Examination, 416 K. of P. Bldg., Indianapolis.

Iowa: * *Examination.* Des Moines, Dec. 6-8. *Endorsement.* Des Moines, Oct. 4. Sec., Dr. M. A. Royal, 506 Fleming Bldg., Des Moines.

Kansas: Topeka, Dec. 15-16. Sec., Board of Medical Registration & Examination, 905 N. 7th St., Kansas City.

Maine: Portland, Nov. 9-10. Sec., Board of Registration of Medicine, Dr. Adam P. Leighton, 192 State St., Portland.

Maryland: *Examination.* Baltimore, Dec. 14-17. *Endorsement.* At the discretion of the Board. Sec., Dr. Lewis P. Gundry, 1215 Cathedral St., Baltimore.

Minnesota: Minneapolis, Oct. 19-21. Sec., Dr. J. F. DuBois, 230 Lowry Medical Arts Bldg., St. Paul 2.

Montana: Helena, Oct. 4-6. Sec., Dr. O. G. Klein, First Nat'l Bank Bldg., Helena.

Nevada: Carson City, Nov. 1. Sec., Dr. G. H. Ross, Industrial Bldg., Carson City.

New Hampshire: Concord, Sept. 9. Sec., Board of Registration in Medicine, Dr. J. S. Wheeler, Room 107, State House, Concord.

New Jersey: *Examination.* Trenton, Oct. 19-22. Sec., Dr. E. S. Hallinger, 28 W. State St., Trenton.

New Mexico: * Santa Fe, Oct. 11-12. Sec., Dr. V. E. Berchtold, 141 Palace Ave., Santa Fe.

New York: *Examination.* Various Centers, Sept. 27-30. Sec., Dr. J. L. Lochner, Jr., 23 South Pearl St., Albany 7.

Ohio: *Examination.* Columbus, Dec. *Endorsement.* Columbus, Oct. 5. Sec., Dr. H. M. Platter, 21 W. Broad St., Columbus.

Pennsylvania: *Examination.* Philadelphia, Jan., 1949. Act. Sec., Mrs. M. G. Steiner, 351 Education Bldg., Harrisburg.

Puerto Rico: *Examination.* Santurce, Sept. 7-11. Sec., Mr. Luis Cueto Coll, 22 Purada, Box 3717, Santurce.

Rhode Island: * *Examination.* Providence, Oct. 7-8. Chief, Div. of Professional Regulation, Mr. Thomas B. Casey, 366 State Office Bldg., Providence.

South Carolina: *Endorsement.* Sept. 6. Sec., Dr. N. B. Heyward, 1329 Blanding St., Columbia.

Texas: Fort Worth, Nov. 4-6. Sec.-Treas., Dr. M. H. Crabb, 1305 Amicable Bldg., Waco.

Virginia: *Examination.* Richmond, Dec. 3-4. *Endorsement.* Dec. 2. Sec., Dr. K. D. Graves, 30½ Franklin Road, Roanoke.

West Virginia: Charleston, Oct. 4-6. Comm., Public Health Council, Dr. N. H. Dyer, State Dept. of Health, Charleston.

Wisconsin. * Madison, Jan. 11-13, 1949. Sec., Dr. C. A. Dawson, Tremont Bldg., River Falls, Wis.

Wyoming: *Examination.* Cheyenne, Oct. 4. Sec., Dr. G. M. Anderson, Capitol Bldg., Cheyenne.

---

* Basic Science Certificate required.

BOARDS OF EXAMINERS IN THE BASIC SCIENCES

Alaska: Juneau. Last week in Aug. Sec., Dr. C. Earl Albrecht, Box 1931, Juneau.

Arizona: *Examination.* Tucson, Sept. 21. Sec., Mr. Francis A. Roy, Univ. of Arizona, Tucson.

Colorado: *Examination.* Denver, Sept. 15-16. Sec., Dr. Esther B. Starks, 1459 Ogden St., Denver 3.

Connecticut: *Examination.* Oct. 9. Exec. Asst., Mary G. Reynolds, 110 Whitney Ave., New Haven 10.

District of Columbia: *Examination.* Washington, Oct. 18-19. Sec., Dr. G. C. Ruhland, 4130 Municipal Bldg., Washington, D. C.

Florida: *Examination.* Gainesville, Nov. 6. Final date for filing application is Oct. 25. Mr. M. W. Emmel, University of Florida, Gainesville.

Iowa: Des Moines, Oct. 12. Sec., Dr. Ben H. Peterson, Coe College, Cedar Rapids.

Michigan: *Examination.* Ann Arbor and Detroit, Oct. 8-9. Sec., Miss Eloise LeBeau, 1510 West Allegan St., Lansing.

Minnesota: *Examination.* Oct. 5-6. Sec.-Treas., Dr. Raymond N. Bieter, 105 Millard Hall, Univ. of Minnesota, Minneapolis.

Nebraska: *Examination.* Omaha, Oct. 5-6. Dir., Bureau of Examining Boards, Mr. Oscar F. Humble, Room 1009 State Capitol Bldg., Lincoln.

Oklahoma: Spring of 1949. Sec., Dr. Clinton Gallaher, 813 Braniff Bldg., Oklahoma City.

Oregon: *Examination.* Portland, Sept. 4. Sec., Basic Science Examining Committee, Dr. C. D. Byrne, Univ. of Oregon, Eugene.

South Dakota: *Examination.* Vermillion, Dec. 3-4. Sec., Dr. G. M. Evans, Yankton.

Tennessee: *Examination.* Memphis & Nashville, Sept. 20-21. Sec., Dr. O. W. Hyman, 874 Union Ave., Memphis.

Wisconsin: *Examination.* Madison, Sept. 25. Final date for filing application is Sept. 18. Sec., Prof. W. H. Barber, Scott & Watson Sts., Ripon.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Malpractice: Abandonment of Patient Without Notice.—The plaintiffs, father and son, sued the defendant physician for damages for alleged malpractice resulting in the loss of the son's leg. From judgments for both plaintiffs, the defendant appealed to the Supreme Court of Appeals of Virginia.

The son fractured his leg in a football game on Oct. 19, 1944, and was taken to the Norfolk General Hospital. It was a simple fracture with slight comminution or splintering. The boy's father engaged the services of the defendant physician, who reduced the fracture and set the leg in a plaster of paris cast in the customary way, with the padding and gauze between the leg and the cast. The next day, when the defendant saw the boy, he was told that the son was suffering excruciating pain in the injured leg and that he had no feeling in his toes. The defendant, according to the plaintiffs' evidence, made no examination of the cast and did nothing about it, however. On October 20 both father and son made a similar complaint. The pain in the ankle had become continuous and unendurable, and the physician was told that there was a throbbing sensation in the patient's ankle, that it felt as though a tight band were around it and that he had no feeling in his toes. The father suggested that the cast was too tight, but the defendant, in very emphatic language, said that it was not. However, he made no examination of the cast or leg and did nothing to alleviate the pain. On October 22, which was Sunday, the defendant left the city for a week, without advising either the patient or his parents of his intention to leave. He did not make any provision for the patient during his absence and did not communicate with him or leave any instructions for any other physician to take care of the case while he was away.

On October 21, the day of the defendant's last visit before leaving town the patient's temperature was 101 F.; at 8 a. m. it was 100.8 F. His temperature had been normal at midnight on October 19, but rose to 101.6 F. at 4 p. m. on October 20; four hours later it was 100.8 F. These temperatures were noted on the chart of the patient. The chart discloses that on October 21 the white blood cell count was 16,000 and the neutrophil count 77 per cent. For twenty-four hours prior to the defendant's last visit to his patient on October 21 the patient had been given morphine on five separate occasions for the alleviation of the pain. On the night of October 21 the son's temperature varied from normal to 102 F., and during the next four days it fluctuated, sometimes being subnormal and at other times up to 103 F. The pain in the ankle was not alleviated by the administration of morphine. On October 30, when the defendant returned, he was again requested to examine the cast and leg, but declined to do so and on the same day discharged the patient from the hospital. The patient was carried to his home at Virginia Beach on October 31 and confined to his bed. The rise in temperature persisted, and he continued to endure extreme pain in his ankle. The father called the defendant on November 7, informed him of the condition of the patient and requested him to see him. The physician refused and told the father that there was nothing wrong with the boy's leg. While the defendant was away, and following his later refusal to see the patient, the patient was treated by Dr. Simpson, another orthopedic surgeon. He testified that the cast was completely bivalved on November 7, for the purpose of relieving all pressure, and that the necrosis was caused by pressure on the nerves, created by the cast. He stated that the possibility of swelling, with the result that the cast might become too tight, even though it were originally properly applied, should be anticipated by a physician and that any unyielding cast applied to a broken limb ought to be viewed with suspicion and examined to see whether it had become too tight. The cast was subsequently removed, on November 27. From that time until July 1946, when it was finally amputated, the leg became progressively worse, and the plaintiff was at no time able to use it.

There was medical testimony that the patient was not in proper condition to have been discharged from the hospital on Oct. 21, 1944, at which time the defendant authorized the discharge. There was medical testimony to the effect that on October 21, the last day on which the defendant saw his patient before leaving on his trip, there was an indication that an infection existed and that a physician with an average degree of learning and skill, practicing in the community, should have attempted to ascertain the cause of the infection and especially should have examined the injured leg and the cast. There was medical testimony to the effect that if a physician intends to leave a case it is his duty to notify the patient, or his parents in this case, of his intention to leave and that he should make some provision to put his patient in charge of some reputable physician. Finally, there was medical testimony to the effect that the amputation of the patient's leg was due to a continuation of the same conditions as were brought about by the swelling of the leg and the failure of the defendant promptly to relieve the pressure by removing or cutting the cast.

The defendant contended that there was no evidence to sustain the verdicts of the jury and that they were founded only on sympathy for the unfortunate boy who lost his leg and for the father who had incurred large expenses. He argued that when he left on October 22 the boy was in the hospital receiving good treatment from the interns and nurses and on October 24 was directly under the supervision and care of Dr. Simpson, an orthopedic surgeon of high standing, and insisted that if he, the defendant, had been in attendance he could have done no more for the patient than was done. He further contended that the fracture was properly reduced and the cast properly applied. The plaintiffs do not claim, said the court, that the fracture was not properly reduced or that the cast was improperly applied. The plaintiffs' contention is that after the application of the cast the defendant neglected to pay heed to certain conditions that arose in a very short time after the cast was applied and, without giving the patient or his father any notice and without securing another physician for the boy, left the city and did not return for eight or nine days, during which time the condition of the patient grew progressively worse.

In cases of this nature, said the Supreme Court, there is no difficulty about the law. It is simple and well settled, although not always easy of application. A physician is not a warrantor or insurer of a cure. His contract is to treat the patient with reasonable diligence and skill. After a physician has accepted employment in a case it is his duty to continue his services as long as they are necessary. He cannot voluntarily abandon his patient. Even if personal attention is no longer necessary in the treatment of an injured limb, the physician, if the case calls for it, must furnish the patient with instructions as to care, and his failure to do so might become actionable negligence.

From the evidence, the Supreme Court continued, the jury reasonably could have found the defendant guilty of actionable negligence in several respects. It could have concluded that on October 20 and 21 the physician should have rendered some kind of treatment when he was notified by the father and the boy of the great pressure of the cast and of the excruciating pain. Failure or refusal to see the patient from October 21 to 30, which was a very critical period, could have been found by the jury to be negligence which proximately contributed to the patient's great pain and suffering and the eventual loss of his leg. The failure or refusal of the defendant to render any treatment after he had been advised of the serious condition of the patient and then sending him home without making any future provision or giving any directions for his care and treatment might have afforded reasonable grounds for the jury to have found negligence on the physician's part in those respects. Finally, on November 7, the defendant failed to respond to the call for medical assistance made by the father for the boy when the physician, by his own admission, had not released the case nor had he been discharged from the obligations he assumed when he took the case. At that time it was his duty to continue attending and treating the patient. His failure in this respect might have been found to have been negligence. We are of the opinion, concluded the Supreme Court of Appeals, that the evidence sufficiently supports the verdicts. Accordingly the judgments in favor of both plaintiffs were affirmed. *Vann v. Harden (two cases), 47 S. E. (2d) 314 (Va., 1948).*

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time Periodicals are available from 1937 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied with stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

*Increased Sugar Tolerance as Factor in Production of Symptom Complex Simulating Peptic Ulcer, Neuro-Circulatory Asthenia, and Psychoneurosis. A. R. Peskin. -p. 92.

Increased Sugar Tolerance in a Syndrome Simulating Peptic Ulcer.—Peskin reports 4 cases in which vague symptoms of a bizarre character were experienced by the patients for several years. Some had a family history of similar complaints. The symptoms were: nervousness, palpitation apprehension, weakness in the legs, tremors, excessive perspiration, mental dulness and hunger pains relieved by food. The symptoms were aggravated or precipitated by physical effort and were prevented or relieved by eating and rest. A study of sugar tolerance suggested itself from the similarity of these symptoms to those of hypoglycemia. Confirmation of the observation that these symptoms were due to relative hypoglycemia was obtained by reproduction of the same symptoms with insulin and exercise. At a relatively high blood sugar level (88 mg. per hundred cubic centimeters) patient began to have such symptoms as tremor, air hunger and discomfort in the pit of his abdomen. More severe symptoms were evident at 74 mg. of blood sugar. A disappearance of symptoms took place with the administration of orange juice. For the prevention and relief of this disturbance the author recommends a high fat and high protein diet. He stresses the practical value of the search for this entity in such obscure diseases as neurocirculatory asthenia, psychoneurosis and peptic ulcer syndrome without positive roentgenologic observations. The role of the liver and thyroid efficiency in the maintenance of a so-called normal sugar tolerance is mentioned. These patients disclosed mild dysfunction of liver and thyroid.

*Treatment of Granuloma Inguinale with Streptomycin. H.L. Hirsh and S.R. Taggart. -p. 159.

Inhalation of Micronized Penicillin for Gonococcal Infections.—Taplin and Thompson say that inhalation of micronized penicillin-glucose or penicillin-plasma mixtures have produced therapeutic concentrations in the blood and urine for more than twenty hours following single inhalations of 200,000 to 300,000 units. Aerosol penicillin inhalations give results similar to intramuscular administration with penicillin-saline solutions. The authors show the apparatus that is used for the administration of micronized penicillin by inhalation and say that 18 of 25 patients with acute gonorrhea who have been treated with inhalation of penicillin were cured clinically and bacteriologically and 3 others were cured clinically, but complete bacteriologic follow-up beyond the first forty-eight or seventy-two hour determinations was impossible to obtain. There were 4 so-called mechanical failures; i.e., patients did not receive the total dosage because of inability to use the large apparatus properly. Retreatments of these 4 failures resulted in three cures and 1 failure. The authors think that this method could cure all but the most stubborn infections.

Penicillin Therapy of Gonorrhea in Women.—Hirschberg made follow-up studies for one to fourteen weeks on 54 women with gonorrhea who were treated with 150,000 units of penicillin in beeswax and peanut oil. There were failures of penicillin treatment in 2 patients. The first of these showed a positive culture seven weeks after receiving 150,000 units of penicillin, the second three weeks after 150,000 units and two weeks after a second treatment of 150,000 units of penicillin. Cultures remained negative after a third dose of 300,000 units. This indicates the importance of follow-up cultures as a criterion of cure.

Streptomycin in Granuloma Inguinale.—Hirsch and Taggart employed streptomycin in 21 patients with granuloma inguinale. The total daily dose was 1 Gm. given intramuscularly in equally divided doses at four hour intervals for periods ranging from six to forty-seven days. Administration of the antibiotic was continued until there was evidence of complete healing of the lesions. The rapidity with which the lesions healed was dependent on their extent and on whether there were moist, ulcerative lesions which were apposed or bathed by vaginal discharge. The Donovan bodies were found to have disappeared from the lesions between the seventh and fourteenth day of therapy. There have been no relapses in the patients followed for up to fourteen weeks. Streptomycin appears to be the drug of choice in the treatment of granuloma inguinale.

Penicillin in Oil and Beeswax in Pediatric Practice.—Adams and Fischer treated 180 children with various acute infections with penicillin suspended in a mixture of peanut oil and beeswax. For the most part, these children were treated as ambulatory patients, necessitating daily visits to the clinic for their injections and follow-up care. Hospitalization was carried out only in cases of severe pneumonia. Once the diagnosis of pneumonia was made, nasopharyngeal and throat cultures were taken. Crystalline sodium penicillin suspended in peanut oil with 4.8 per cent bleached beeswax was used. This was supplied in 10 vials containing 300,000 units per cubic centimeter. All patients received 5,000 units per unit of weight at each injection. There were 100 cases of pneumonia, 32 of which occurred in infants under 12 months of age. The results achieved were satisfactory, with 92 good responses, 4 poor responses and 4 failures. Twenty-nine cases of suppurative otitis media, 9 of which proved to be sulfadiazine-resistant, were also treated. There was only 1 failure in this group. The penicillin blood levels obtained by this method of injection were extremely variable. Two instances of mild local inflammatory reaction at the site of injection were encountered. Both cleared spontaneously without formation of abscess. There were no allergic reactions.

Pulmonary Vascular Obstruction in Tetralogy of Fallot.—Rich shows that widespread and progressive thrombosis of pulmonary vessels of microscopic size is a frequent occurrence in patients with congenital pulmonary stenosis (tetralogy of Fallot type). This condition was present in all but 2 of 21 consecutive cases studied at necropsy. It is suggested that the predisposing factors are the increased viscosity of the blood, resulting from the compensatory polycythemia, and the reduced rate of flow in the pulmonary vessels, resulting from the greatly diminished amount of blood delivered to the pulmonary vascular system.

Does Pertussis Activate Tuberculosis?—Toomey and his co-workers reviewed all cases of pertussis admitted to the Contagious Disease Hospital of Cleveland from 1938 to 1947. There were 1,747 patients admitted with pertussis. In 38 patients there was some connection with tuberculosis, and these constituted the basis for the investigation. Twenty-three had positive reactions to the tuberculin test; 3 older children with positive reactions had negative roentgenologic observations, while 19 actually had tuberculosis. With the exception of 1 case no evidence could be found on which to base the conclusion that the tuberculosis was activated by the pertussis. It cannot be said that pertussis does not possibly activate this disease, but all evidence is to the contrary. Reactivation of tuberculosis following pertussis occurs so infrequently that it is probably a coincidence. The authors recommend, however, that every patient ill with whooping cough, especially Negro children, should have a tuberculin test at the onset of the pertussis. Every patient ill with whooping cough who coughs longer than a month should have another tuberculin test, for if he does not have bronchiectasis he may have tuberculosis. In the presence of acute whooping cough or measles, a roentgenologic diagnosis of miliary tuberculosis can never be made if the reaction to the tuberculin test is not known, for the roentgenologic features of the lungs of a patient ill with whooping cough, or measles at the height of the rash, often cannot be differentiated from those produced by miliary tuberculosis.

Congenital Hemolytic Icterus.—Hageage and Horgan present histories of 2 girls, cousins, who had familial hemolytic anemia or acholuric jaundice. Evidence that heredity plays a part in this disease was provided by the fact that the disease appeared in two first cousins (splenectomy), their aunt (splenectomy), their grandmother (icterus-anemia) and their great grandmother (icterus-anemia), all maternal, representing four generations of the same family. If this condition is diagnosed in a patient the blood of all members of his family should be examined. Blood transfusions give no sustained improvement and are palliative. Early splenectomy, followed by transfusions, promotes convalescense and sustained improvement.

Urethane in Leukemia.—Wilson and his associates report on the preliminary results of urethane therapy in 27 patients with leukemia or allied conditions. The best results were obtained in 7 patients with chronic myelogenous leukemia. On the whole, urethane produces about the same clinical hematologic results as standard roentgen therapy. The therapeutic response of chronic lymphatic leukemia is less satisfactory and more variable than that observed in chronic myelogenous leukemia. The clinical course of the acute leukemias is not affected by urethane. Polycythemia vera responds only partially to the drug. One case of reticuloendotheliosis and 1 of multiple myeloma were treated, and the clinical course of the disease was not affected in either instance. Nausea and anorexia are frequent when the drug is given orally. Other toxic effects have been noticed. Further investigations are necessary to establish the proper procedure, dosage, toxic levels and modes of action of urethane.

Neurogenic Bladder of Poliomyelitis.—Involvement of the urinary bladder and colon occurs in 10 to 20 per cent of the cases of acute poliomyelitis. Temporary paralysis of the bladder occurred in 8 per cent of the cases of poliomyelitis seen at the University of Kansas Medical Center during the 1946 epidemic. Cystometric studies on patients with poliomyelitis convinced the author that this type of neurogenic bladder is produced by poliomyelitis. This is the first description of cystometric aspects of the neurogenic bladder of poliomyelitis. He suggests that the term motor neurogenic bladder of poliomyelitis be applied to this condition. Generally the bladder dysfunction, like the atony of the colon, is of short duration and can be relieved by intermittent catheterization or use of an indwelling catheter for a few days. The author, however, observed a case of permanent paralysis of the bladder in a boy aged 16. Cystometric examination on numerous occasions revealed an atonic neurogenic bladder In spite of many attempts at voiding, this patient was never able to elicit a voiding contracture. Resection of the internal sphincter likewise was futile. One year after the onset of the disease he was still on catheter drainage and had shown no appreciable improvement in the extensive paralysis of his lower extremities. There was complete motor paralysis of both legs, thighs and hips without sensory loss. Vesical calculi were crushed transurethrally on three occasions.

Wilms' Tumors.—Sauer believes that with a few exceptions kidney tumors of children, described as sarcomas or carcinomas, belong to the Wilms type of malignant new growth. The complexity of the histologic picture accounts for the confusing terminology which includes terms like adenosarcoma, embryonal sarcoma, teratoma, myochondrosarcoma and rhabdosarcoma, or myxosarcoma. Although Wilms' tumors comprise approximately 20 per cent of all malignant neoplasms in children, only 16 children with this type of tumor were admitted to the Roswell Park Memorial Institute during a thirty year period. This represents an incidence of only 1 case in about 3,500 admissions. Pathogenesis, clinical course, symptoms and diagnosis of the disease are discussed. The prognosis is poor, with an ultimate mortality rate of close to 90 per cent. The duration of life averages less than one year after the diagnosis is made. Removal or complete destruction of the tumor before development of metastases is imperative. Prompt surgical treatment followed by postoperative irradiation is advocated in small, movable tumors. Preoperative irradiation is advisable in fairly large or apparently inoperable lesions, in an attempt to attain sufficient shrinkage to make the tumor operable. Removal of the tumor in such cases should be followed by supplementary postoperative irradiation. Inoperable tumors should be treated by radiation alone. Favorable results and even cures may be accomplished by irradiation in certain radiosensitive tumors of this type. The author reports the case of a white girl, aged 2 years, in whom an inoperable Wilms' tumor was cured following irradiation therapy exclusively. The last series of roentgenologic treatments terminated in October 1939, and the girl has been in good health since that time.

Cultivation of Toxoplasma in Chick Embryo.—McFarlane and Ruchman used the R.H. strain of toxoplasma, which had been isolated by Sabin from a fatal human case of encephalitis. It had been maintained by continuous intracerebral passages in mice. Material from passages 304 to 344 was used for initiating the cultures in embryonated eggs. Injection of toxoplasma-infected mouse brain suspensions into the yolk sac of embryonated eggs on at least six different occasions led to multiplication of the parasites with resulting death of the embryo in four to ten days after inoculation. Smears of the chorioallantoic membrane and the yolk sac stained with Wright's stain revealed numerous toxoplasma both free and intracellular.

Muscular Fatigue and Histamine-Provoked Ulcer.—Lillehei and Wangensteen say that complete physical rest is frequently mentioned by internists as a valuable adjunct in the medical management of peptic ulceration. This precept has been derived primarily from clinical observation. The authors report observations on the effect of moderately severe muscular fatigue on the incidence of the histamine-provoked ulcer and on gastric secretion in dogs. The animals were run from three to four hours consecutively each day on five to six successive days on an electrically driven endless belt treadmill. The dogs were allowed a ten minute rest period each hour and as much water as they wanted. The results indicated that moderately severe muscular fatigue abets the histamine-provoked ulcer quite appreciably, while at the same time depressing the output of hydrochloric acid. These seemingly paradoxical observations would suggest that the ulcer-abetting effect of muscular fatigue is an effect on the mucosa itself (most probably on its blood supply) which renders it more vulnerable to the digestive action of the acid-pepsin mixture.

Antigen Derived from cultivation of Toxoplasma in Egg.—Warren and Russ found that inoculation of embryonated eggs with toxoplasma resulted in a generalized parasitic disease of this host with a fatal termination. The agent could be maintained by serial passage of embryo brain. Chorioallantoic membranes from infected eggs contained a stable, specific soluble antigen which fixed complement with toxoplasma-immune animal serum. Human serums from cases of toxoplasmosis which were known to contain neutralizing antibody against the parasite also fixed complement with chorioallantoic membrane antigen.

Splenectomy in Schistosomiasis.—Noya Benítez has performed splenectomies on 20 patients who were in the preascitic stage of Banti's syndrome due to schistosomiasis. All patients manifested improvement in general health and well-being, their blood counts, hemoglobin level and platelet counts having gone up to nearly normal limits and their liver function tests showing considerable improvement. Three patients had postoperative hematemesis, but all recovered under conservative treatment. There were no deaths in this series. The results obtained in this series and observations made in other clinics show that splenectomy is indicated and is the treatment of choice in cases of Banti's syndrome due to schistosomiasis.

Rabies.—In dogs as in human beings there occur two types of symptoms, the furious and the dumb. The incubation period varies between four weeks and ten months. It is generally accepted that paralytic rabies is more likely to develop after a minor and insignificant bite. In untreated patients with severe bites typical furious symptoms usually develop. Paralytic rabies runs its course in between seven and one half and twelve days, while in furious types the average course is three days. The treatment of rabies comprises two phases, local therapy and prophylactic immunization. Local treatment consists of cleaning the wound and cauterizing it. In the prophylactic treatment against rabies, known as the Pasteur treatment, vaccines are used which consist of emulsions of rabbit brain or spinal cord containing either living or killed fixed virus. The Semple method of phenol-killed vaccine is most commonly employed. This vaccine consists of a four per cent emulsion of nervous tissue in physiologic saline containing phenol in 0.5 per cent concentration. The methods of administration will vary somewhat, but with the Semple vaccine it is recommended that 2 cc. be given subcutaneously daily for a total of eighteen to twenty-five injections. Patients bitten on the extremity or trunk receive eighteen injections, while those bitten on the head, face or neck receive up to twenty-five injections. Pasteur's treatment is indicated in any person who has been bitten or scratched by a rabid animal or in whom the saliva of such an animal has reached an open wound. Any one bitten or scratched by a stray dog in which the presence of rabies cannot be excluded should also be treated. After commenting on the use of ultraviolet irradiation in the production of potent inactivated vaccine, the author stresses that, since dogs represent the main disseminating factor of rabies virus, interruption of the cycle involves the control of the disease in dogs. It is impossible to depend alone on vaccination of dogs. Hobel, who found wide variability in the protective action of commercial vaccines, developed the Hobel test of potency of vaccines, which has been generally adopted as a prerequisite before offering any commercial vaccine for sale in the United States. Since stray, homeless dogs do not receive vaccination, they should be destroyed. Sentimental and ignorant pet owners have created some public opinion against the fulfilment of strict control of pets, but they should not be permitted to jeopardize the health of others.

Tantalum Mesh in Repair of Ventral Hernias.—According to Koontz, the repair of large ventral hernias has always taxed the ingenuity of the surgeon. This is true not only when the defect is large but when the fascial structures surrounding a smaller defect are weak. Most of these defects occur in extremely obese persons. The fascia surrounding the defect is often weakened by the infiltration of fat, and this militates against a successful repair by any of the ordinary methods. In experiments on dogs 3 to 6 inches (7.6 to 15 cm.) of the rectus muscle on each side was resected, and the defect immediately repaired by suturing a piece of tantalum gauze to the edges of the fascia surrounding the defect. These animals were killed from four and one-half to nine and one-half months after operation. In each instance the defect was completely closed by the mesh, which had become covered by a thick and tough envelope of fibrous tissue. The fibrous tissue had grown through the meshes of the gauze everywhere and could not be separated from the gauze except by sharp dissection. Subsequently the author used the tantalum mesh in 5 obese patients with exceedingly large hernias. The results have made the author enthusiastic about this material. He mentions other surgeons who have used it and concludes that tantalum mesh will prove a most valuable material in the repair of large and difficult ventral hernias.

New Trivalent Antimony Compound in Granuloma Inguinale.—The new trivalent antimony compound which Allison used in the treatment of 65 Negro patients (32 women and 33 men) with granuloma inguinale is lithium stibiothiomalate. The drug was administered by intramuscular injections in dosages of 3 cc., equivalent to 30 mg. of antimony, twice weekly. Injections in the buttock were painless and gave no more local tissue reaction than that from "fuadin." The largest number of injections administered was forty-two; the smallest was five. The majority of patients received approximately twenty injections. Reactions do occur. Once a patient becomes intolerant of one trivalent antimony compound, he usually becomes intolerant of other forms. A few patients tolerate one antimony compound better than another. Adequate food, vitamins and iron intake, a daily cleansing bath and bowel evacuation are as necessary as drug therapy.

Testosterone in Advanced Stage of Cancer of the Breast.—Davison and Letton administered androgen in the form of "oreton" to women with cancer of the breast. They began with 50 mg. per day, reducing this dose later to 50 mg. three times per week. They have watched the blood chemistry of the patients, the estrogen level as judged by vaginal smears and the change in the metastases by roentgenograms as well as by biopsies. Seven of 8 patients obtained some degree of relief of pain and gained some weight on this therapy. Four of these 8 "hopeless" patients have returned to their regular occupations after taking large doses of testosterone. One patient with soft tissue metastases only had excellent results persisting for over fifteen months. Apparently the treatment is of temporary value only. If omitted there is a return of activity of the cancer. Biopsy shows that the cancer is being "choked" by a proliferation of fibrous tissue and that the cells, although still viable, are pyknotic and of reduced activity. Good results are found in patients with depression of estrogenic activity, poorer results in patients who still show estrogenic activity after receiving testosterone. Masculinizing effects were noted, but the patients did not object when they realized the other beneficial results. The authors believe that any patient with metastatic carcinoma of the breast not only should have the usually accepted treatment of surgery and radiation but should be given the benefit of a trial on large doses of testosterone with careful follow-up.

Treatment of Bleeding Peptic Ulcer.—Holman cites the case of a patient who died five days after the onset of bleeding from a peptic ulcer. The sequence of events in this patient is typical of several that were witnessed each year under a conservative therapeutic regimen. A survey was made, which led to the abandonment of conservative treatment in favor of immediate operation for certain groups of patients. The author compares the results under this more radical therapy with the results under the earlier conservative therapy. During the earlier period, patients admitted because of severe hemorrhage from ulcer were treated with complete rest in bed, nothing by mouth, adequate sedation and supportive parenteral fluids until the bleeding had stopped. Those who continued to bleed under this treatment also received repeated blood transfusions. Twenty-one, or 13 per cent, of these patients died. The problem was to recognize those patients who would not benefit from conservative treatment. Critical analysis revealed a poor prognosis for two groups: those who failed to improve within forty-eight hours after they had been placed on a strict medical regimen and those who suffered the first hemorrhage while they were under a medical regimen. Age seemed important. In patients under 30 years of age the mortality was 6 per cent, in contrast to 20 per cent in those 50 years and older. In view of these observations it was decided that any patient who fell into either of the two groups described, particularly if he were over 40 years of age, would be operated on immediately if the condition warranted the risk. A survey of the period from 1940 to 1946 during which the newly instituted treatment regimen was followed showed a fall in the mortality from the previous 13 per cent to 5 per cent. Gastric resection is tolerated surprisingly well if a large amount of blood is given before, during and after the operative intervention. Resection is the ideal procedure to insure both immediate control of bleeding and a satisfactory permanent result. Indirect methods such as gastroenterostomy and plastic procedures on the duodenum have little value. Gastric resection offers the best protection against future hemorrhage

Glossopharyngeal Nerve in Carotid Sinus Reflex.—Ray and Stewart cite evidence pointing to the important role of the glossopharyngeal nerve in the carotid sinus reflex in man, but they show that with insufficient evidence to conclude that this nerve alone comprised the principal afferent pathway in the case of the hypersensitive carotid sinus syndrome, the crucial experiment called for intracranial division of the nerve in a patient with the syndrome. In 1942 Herbert and associates reported their experience with division of the glossopharyngeal nerve in a man aged 64 with a hypersensitive carotid sinus. The carotid sinus reflex previously induced by pressure over the sinus was abolished on the side of the nerve section. The authors report 3 cases in which the glossopharyngeal nerve was divided intracranially on one side for relief of carotid sinus syndrome. They conclude that: (1) the glossopharyngeal nerve transmits the afferent impulses of the carotid sinus reflex induced by pressure on the carotid sinus; (2) intracranial division of the glossopharyngeal nerve permanently abolishes the effects of pressure on the homolateral carotid sinus; (3) the chemically induced part of the carotid sinus reflex probably remains intact after intracranial division of the glossopharyngeal nerve; (4) as an alternative procedure to local denervation of the carotid sinus for relief of the carotid sinus syndrome, intracranial glossopharyngeal nerve section has an advantage in that the former procedure may be followed by regeneration of the nerves and possesses the hazard of damage to the carotid artery, and (5) intracranial division of the glossopharyngeal nerve can be employed in patients in whom the condition of the local tissues about the carotid sinus might make local surgery undesirable or impossible.

Radical One Stage Pancreaticoduodenectomy.—Child says that during the twelve years which have elapsed since Allen O. Whipple and his associates announced their initial success in extirpating the duodenum and the head of the pancreas, the original two stage operation has undergone many modifications. In November 1943 Child reported a one stage procedure which was justly criticized by Whipple not only because drainage of the biliary tract was reestablished by means of the gallbladder but because this anastomosis was placed distal to that between the stomach and the jejunum. The operation was promptly changed to one in which biliary drainage was obtained by way of a choledochojejunostomy placed proximal to the gastroenterostomy. This operation was performed in 22 patients. In this one stage procedure it was found helpful to have clearly in mind a series of steps which, if followed in orderly progression, contribute materially to shortening and facilitating a procedure which is always long and arduous. The initial features of this operation are the maneuvers directed toward determining, if possible, whether or not the superior mesenteric vein is compromised by the tumor. It can be hoped that eventually some successful method of avoiding the necessity of preserving this structure may be devised, for it is certainly the weakest point as well as the most frustrating in the entire operative attack on pancreatic cancers. Indication that it may be sacrificed is to be found in a case reported by Brunschwig and in a patient in this series in whom postmortem examination five days following division of the superior mesenteric vein failed to reveal any significant venous engorgement of the small bowel.

Intramedullary Fixation in Fractures of Femur.—Wiggins and Lewis found internal fixation of fracture by means of the intramedullary nail after the method of Kuntscher useful in the treatment of certain fractures of the femur; they report 6 cases of fractures of the femur treated by intramedullary fixation. Internal fixation by means of the intramedullary nail may be substituted for other methods of *fixation* when open reduction is necessary. Intramedullary fixation is indicated in femoral fractures when closed reduction has failed, or in those which for other reasons must be openly reduced. The method has been useful in handling several femoral fracture problems; e. g., acute fractures of the upper third of the shaft, old unreduced fractures, old nonunions and shaft fractures in paraplegic persons. The *advantage* over other *methods of* internal fixation are: a technically easier operative procedure; a shortened operative time; a lowered operative and postoperative morbidity; obviation of plaster immobilization, and a shortened healing *time* with earlier ambulation. *Two serious* complications have been seen, refracture and bending of the nail. The refracture occurred in the paraplegic patient when it became necessary to extract the nail after three months. The nail should not be removed before trabeculation is established. In spite of postoperative immobilization there was decided bending of the nail at the fracture site in 1 case It appears that the rolled sheet stainless steel nail available to the authors is not strong enough to provide satisfactory fixation in all persons. The European literature describes the use of a much heavier nail. With the type of nail used *in this series* light skeletal balanced traction, with exercise of the joints, should be maintained until the patient is ready for a brace An ischial weight-bearing caliper should be worn until solid union is present. Eventual extraction of the nail would seem desirable, but the literature does not indicate that it is requisite.

Streptomycin in Laryngeal *Tuberculosis.*—In the first of the 2 patients treated by McGovern and Broome, examination of the larynx showed a large ulcerated lesion involving the right arytenoid and right ventricular band. Roentgen examination of the chest showed tuberculous infiltration in the upper part of the left lung. Under local sulfonamide therapy the ulceration increased in size and *depth.* The patient was given 1 Gm. of streptomycin divided in six doses intramuscularly each twenty-four hours for one week, and then 1.5 Gm. daily for nine weeks. The streptomycin was also administered as a laryngeal spray every four hours. At the end of two weeks the ulceration showed improvement and the pain was relieved, and at the end of one month the ulcer had completely healed. Roentgen examination of the chest showed improvement in the left lung. There were no toxic vestibular or other effects of the drug. Examination of the throat of the second patient before the initiation of streptomycin therapy revealed an enormous pale, infiltrated, ulcerated, turban-shaped epiglottis; the interior of the larynx could not be seen. Streptomycin therapy was started as in the first patient. The throat has improved steadily but is not yet normal. Inasmuch as the laryngeal lesion in the first case had become progressively larger up to the time of treatment with streptomycin and then healed so promptly, the authors had little doubt that the streptomycin was the causative *factor.* The striking symptomatic improvement in the second case illustrates the value of this form of treatment in obstinate cases of tuberculosis.

Lateral Aberrant Thyroid Tumors.—Black points out that it is widely believed that the tumors of obvious thyroid origin which are occasionally seen in the lateral cervical regions arise from the lateral thyroid anlagen and, hence, are properly called lateral aberrant thyroid tumors. The early view that these tumors were benign has been modified, and the concept that the lateral cervical tumors are metastatic is of more than theoretic importance. Review of 112 cases of papillary adenocarcinoma of the thyroid gland treated at the Mayo Clinic from 1939 to 1945, inclusive, revealed that the lateral cervical papillary tumors are metastatic lesions from a primary papillary adenocarcinoma of the thyroid gland. The malignant nature of the primary lesion in the thyroid is well illustrated by the number of local recurrences that follow subtotal lobectomy. If the papillary adenocarcinoma is larger than a few millimeters in diameter, and if it is recognized during the operation, a total rather than a subtotal lobectomy should be performed. Although subsequent operations to remove involved cervical lymph nodes were not infrequently necessary, the author believes that the removal of only the involved lymph nodes, generally as a group, is sufficiently radical treatment of the metastatic lesions. Examination at stated intervals after the operation to determine whether unremoved lymph nodes have become palpable is necessary. In addition to the fact that a primary papillary adenocarcinoma was found in every case in the series, the fact that the primary lesion was always present in the corresponding lobe of the thyroid gland is of importance from the point of view of treatment.

Repetitive "Lipiodal" Tubal Insufflations.—Rutherford reports on 417 patients who were studied over a period of five years. They presented themselves with either primary or secondary sterility and were unselected other than by their wish to have a child. They were 19 to 41 years of age. The women were proved to be habitually ovulating; they had no physical defects detectable by the usual methods, and their only cause of infertility was tubal occlusion diagnosed on two failures of air insufflation. The woman was taught to calculate her fertile period. Rubin's test was done between the eighteenth to sixteenth day before the first day of the next calculated period. If air failed to pass at a pressure of 200 mm. of mercury, a repeat Rubin test was done five to seven days later. If, on the second air insufflation, no fall in pressure was obtained, the patient was scheduled for oil insufflation during the following fertile period. Iodized poppyseed oil 40 per cent was introduced by means of a Luer-Loc syringe and two roentgenograms were taken. The uterotubograms were done once monthly until tubal patency was established, or until three consecutive efforts failed to demonstrate continued progress in opening the tubes. Patency was achieved in 71 per cent of the women, and pregnancy resulted in 63 per cent. The dangers of the procedure are outlined, as well as the need for proper selection of cases and for the timing of the procedure.

Generalized Scleroderma: Report of Case. A. N. Reis. -p. 299.

Management of Edema.--Pohle and McKitterick stress that rational therapy of congestive heart failure with its attendant edema should consist of rest and digitalis for the failing myocardium, adequate restriction of sodium intake and mobilization and removal of the retained sodium. Simple restriction of water will accomplish nothing but will make the patient thirsty and press cellular dehydration to the danger point. Sodium restriction in order to be effective in the average case must be kept to a daily intake of about 2 Gm. as sodium chloride. If no salt is added in cooking, the salt intake falls to 3 or 4 Gm. per day. Thus a special diet becomes necessary. The one which was first suggested by Newburgh and modified by Schemm combines two desirable features. It not only adequately restricts sodium but combines foods in such a manner that the metabolic result is an excess of acids which combine with sodium and take it to the kidney where some is excreted. This last feature is important because sodium must be kept mobilized if proper water balance is to be maintained. The authors have used this diet during the last five years and have obtained uniformly favorable results with it. They show that the acidifying agents and mercurial diuretics are useful in the initial clearing of edema but become impractical when used over long periods. The low sodium acid ash diet furnishes an efficient practical means of restricting sodium intake and promoting adequate sodium excretion over long periods. During a five year experience with the low sodium acid ash diet it has seldom been necessary to administer further acidifying agents or mercurial diuretics after edema has once been brought under control. Liberal water intake abolishes thirst, protects against azotemia and maintains adequate urinary output to insure optimum excretion of sodium.

Calciferol in Cutaneous Tuberculosis.—Powell and his associates report observations on 12 patients with cutaneous tuberculosis treated with calciferol. The drug was given by mouth either in doses of 50,000 units three times daily together with calcium or in doses of 600,000 units twice weekly. In some instances first the one and then the other method was used. The 12 patients have been under treatment for nine months or longer. Six were cured, 3 were much improved, 2 showed little improvement and 1 showed no response. Results obtained with calciferol in larger groups by other investigators indicate that about 60 per cent of patients will be cured and an additional percentage will be improved. The authors describe the effects of calciferol on the blood chemistry and suggest that the therapeutic effects are due to the increase in the body's resistance. It does not seem to have any direct toxic effect on the tubercle bacillus. In cerebral tuberculomas and in tuberculous meningitis it was without effect, but in bronchopneumonic phthisis it produced some improvement. Calciferol produced some improvement in the general condition in a patient with pemphigus vulgaris. In a patient with lymphocytoma, in whom a lesion had been improved by roentgen treatment, calciferol was used for a fresh lesion and effected healing in four months. A case of granuloma annulare failed to respond to calciferol, but a case of multiple myelomatosis improved while on calciferol.

Difficult Case of Stress Incontinence. T.L. Chapman. -p. 49.
*Osteomalacia Associated with Steatorrhoea: Report of Case. D.W. Short. -p. 53.

Osteomalacia Associated with Steatorrhoea.—Short reports a case of osteomalacia in a woman aged 50. Chronic invalidism and severe deformities resulted in a comparatively short period of time. The onset of the disease about six years ago was characterized by asthenia so extreme as to simulate paralysis, and this was followed by progressive skeletal changes. There is no history of tetany, nor was there clinical evidence of it when she was examined later. Since osteomalacia is so frequently associated with and exacerbated by child-bearing, it is interesting that the patient had ten pregnancies within the space of sixteen years without any evidence of the disease. Her diet appears to have been adequate, and the deficiency seems to have been due to defective absorption of calcium from the bowel. She has a persistent steatorrhoea, which may be due to a pancreatic insufficiency. The author has observed 2 other probable cases of osteomalacia in recent months. This disease especially in less gross forms, is not uncommon and should be borne in mind as a possible cause of skeletal dystrophy in adults.

Crush Syndrome and Traumatic Uremia. J. H. Hicks. -p. 286.
Chronic Bilateral Spontaneous Pneumothorax: Difficulties in Treatment. C. F. Hawkins. -p. 288.

Epidemiology of Poliomyelitis.—Horstmann shows that the epidemiology of poliomyelitis still presents many challenging problems. In spite of all the information collected by many investigators in many lands we still cannot say why poliomyelitis suddenly became epidemic almost sixty years ago, why it is increasing rather than decreasing like other infectious diseases, why it is a summer disease with a preference for certain lands, how it is spread or how it may be prevented. Research on poliomyelitis must be continued.

Tuberculous Cystitis.—In each of the 4 cases reported by Pybus and Jones tuberculous cystitis developed or persisted after removal of a tuberculous kidney and was treated by transplantation of the remaining ureter into the pelvic colon. In none was there evidence, at the time of transplantation, of tuberculosis in either the remaining kidney or its ureter. Three of the 4 patients were alive from three to nearly five years after the transplantation. The fourth patient died fifteen months after operation, the exact cause of death being unknown. The results in these cases seem to justify more frequent use of this operation.

*Severe Hypertension in Young Persons: Study of 50 Cases. R. Platt. -p. 83.

Idiopathic Pulmonary Hemosiderosis.—Wyllie and his associates regard idiopathic pulmonary hemosiderosis or essential brown induration of the lungs as rare; they were able to find reports of only 17 cases in the literature up to 1947. They review 7 additional cases which were observed between 1938 and 1947. The condition seems to commence usually in early childhood, often in infancy. There appears to be no hereditary predisposition. The clinical signs are periodic attacks of dyspnea and cyanosis, associated with hypochromic anemia with hemolytic features. Hemoptyses, hematemeses and abdominal pain may be present. Physical signs in the chest are insignificant by comparison with radiologic signs. Changes are confined to, or maximal in, the lesser circulation. Myocardial changes, if present, are insufficient to account for the pulmonary lesions. Anemia is secondary, and in some instances there is even a compensatory rise in the red blood cell count when anoxemia with dyspnea and cyanosis supervenes in the final stages of the disease. Increase of reticulin, collagen and muscle, and decrease of elastic fibers in the pulmonary interstitial tissue lead to lack of distensibility of the lungs with consequent peripheral stasis in the capillary bed. This is followed by hemorrhage by diapedesis and deposition of hemosiderin. The onset is insidious. The intermittent periodic course and the increasing severity of the clinical picture are explained by the fact that ever larger portions of the lungs become affected. Anoxemia leads to dyspnea and cyanosis. Hemoptyses and hematemeses may occur. Subpleural hemorrhages, particularly in the region of the diaphragm, may give rise to referred abdominal pain. Hemosiderin deposits, fibrosis and areas of collapse are the pathologic basis of the radiologic appearances. Pulmonary hemosiderosis is not part of a generalized hemosiderosis and has no relation to hemochromatosis, since there is no general disturbance of iron metabolism. The prognosis is bad. Although 5 of the 7 patients whose histories are reviewed are alive, only 1 is in fairly good general condition.

BAL in Arsenical Dermatitis.—Carleton and his associates give an account of 44 cases of arsenical dermatitis treated with 2,3-dimercaptopropanol (BAL); 41 of these infections were of the acute exfoliative type. Three cases ended fatally, and in 4 more it was impossible to assess the progress numerically. In the remaining 37 cases the mean number of days between the first injection of BAL and healing or practically complete healing was 21.5 days. Abscesses at the injection sites developed in 8 cases.

Severe Hypertension in Young Persons.—Platt reports 191 personally observed cases of hypertension, to which have been added 5 cases of latent or chronic nephritis, in which hypertension was present. These cases form a consecutive and unselected series studied during the last thirteen months. Among the 191 cases of severe hypertension 45 occurred in persons under the age of 40 years. Of these, only 13 appeared to be cases of essential hypertension. No case of malignant hypertension in a patient under 34 years was seen. Young persons with the malignant type of hypertension nearly always have secondary hypertension, the underlying cause of which is often pyelonephritis, which may be on the background of a congenital abnormality. When cases of secondary hypertension were excluded, the average ages of patients with malignant and benign hypertension in the present series were 45.2 and 53.2 years, respectively. Taking into account the likelihood that patients with benign hypertension do not complain of symptoms for many years after their disease begins, it seems probable that benign and malignant hypertension have a similar age of onset. It is generally assumed that in persons under the age of 35 years, chronic nephritis is the commonest cause of hypertension. The author's experience is the reverse of this, since only 5 cases of chronic nephritis were observed during the time that these 24 cases of hypertension in patients under 35 years of age were collected. It is possible that many cases of hypertension are wrongly diagnosed as chronic nephritis.

Morphine in Diseases of Heart, Indications and Contraindications. A. Schrumpf. -p. 81.
•Ambulant Vitamin E Therapy in Diseases of Heart. N. J. Gram and V. Schmidt. -p. 82.

Electrocardiographic Signs of Myopathy in Neurasthenia.—In 10 of 46 cases of neurasthenia Veflingstad found changes in the coronary part of the electrocardiogram in the form of low or negative T waves on several leads. There were no signs of organic heart disease, and subjective cardiac symptoms were slight The changes are regarded as purely functional and due to a preponderance of sympathicotonic impulses on the coronary circulation.

Heart Disease in Thyrotoxicosis.—Vogt states that of 419 patients with thyrotoxicosis treated in Drammen Hospital from 1935 to 1944 45, or 10.7 per cent, 4 men and 41 women, had cardiac disease with auricular fibrillation, enlargement of the heart or cardiac insufficiency. Thirty-eight patients underwent operative intervention, with subtotal strumectomy in 31 and hemistrumectomy in 7. Follow-up after an average of four years showed that 32 of the 38 patients were living, 5 still had thyrotoxicosis but were considerably improved, while 27 had no thyrotoxicosis. The late prognosis for patients not operated on was poor in most but not all cases. After the usual preoperative treatment strumectomy was tolerated remarkably well even by patients with considerable cardiac insufficiency. There were 3 postoperative deaths; recurrence was observed in 3 cases. Among the 27 patients without thyrotoxicosis cases of cardiac insufficiency were reduced from 9 to 1, cases of continuous fibrillation from 12 to 3, and intermittent fibrillation had disappeared. Improvement in work capacity paralleled the improvement of insufficiency. In most cases no other cause of the heart disease than the thyrotoxicosis was demonstrable; in a minority of cases there was evidence that it depended on hypertension, valvular defect or coronary sclerosis.

Myxedema Heart and Other Cardiac Symptoms in Hypothyreosis.—Hypothyreosis is often accompanied by cardiac symptoms either due to hypothyreosis itself or appearing as a more independent complication. Most important are the so-called myxedema heart and coronary sclerosis; they may appear in combination. Myxedema heart is often associated with myxedema and disappears on specific treatment simultaneously with the other symptoms of myxedema. The electrocardiographic changes in myxedema heart agree with the establishment of fluid in the pericardium, shown by a number of investigators to be the cause of the large heart of myxedema. There are probably also functional changes. The roentgenologic and electrocardiographic changes due to coronary sclerosis, true hypertrophy and fibrosis are irreversible. Ten cases of hypothyreosis are reported in women aged from 37 to 73 who have been treated during the last two years. Four had myxedema, 2 of these with the fully developed myxedema heart, 2 with the early form. In 1 patient with well established myxedema and signs of coronary sclerosis a fatal cardiac infarct occurred during thyroid treatment; 1 patient reacted to the treatment with fibrillation, 1 with postoperative hypothyreosis had paroxysmal tachycardia during treatment, and in 1 of the myxedema patients the supraventricular extrasystole present before treatment disappeared during thyroid medication

Ambulant Vitamin E Therapy in Diseases of Heart.—Gram and Schmidt say that they cannot confirm the Canadian results of this therapy in cardiac disease. "Ephynal" (synthetic vitamin E) gave no improvement in 63 of 80 patients, mainly with arteriosclerotic disease of the heart. Five patients showed definite improvement, and in 12 there was subjective improvement which cannot with certainty be ascribed to the vitamin. The effect observed, if due to vitamin E, must be assumed to depend on improvement in the condition of the blood vessels, especially of the coronary vessels, and must be considered as purely local.

35:157-182 (Jan. 23, 1948. Partial Index

*Galli Mainini's Test for Pregnancy. R. M. Pinto and H. J. Suer Boero. -p. 165

Galli Mainini's New Test for Diagnosis of Pregnancy.—The male tóad, Bufo arenarum Hensel, is used for the test, which consists of microscopic examination of the toad's urine, obtained from the toad's cloaca, after the animal is given a subcutaneous injection of 10 cc. of the morning urine of the woman suspected of pregnancy. The response is observed in two to three hours. Positive result consists of the appearance in the toad's urine of spermatozoa. Pinto and Suer Boero carried out this test on the urines of 158 pregnant women, 16 women in labor or puerperium and 80 women with gynecologic disease. The test has the advantages of being simple, rapid, specific and economical. False reactions do not occur. It is advisable to use two male toads for each test. The test gives negative results during labor and puerperium and in cases of hydatidiform mole, even when the Friedman reaction in the last mentioned case is positive.

*Vagotomy for Ulcers (Dragstedt's Operation). A. Monsaingeon. -p. 303.
Considerations on Ventricular Hydrocephalus. M. Feld. -p. 317.
Some New Points of View Concerning Protein Diet in Course of Infections and Surgical Conditions. J. Trémolieres and G. Péquignot. -p. 320.

Vagotomy for Ulcers.—Monsaingeon discusses Dragstedt's operation on the basis of reports in the literature and of 6 cases in which section of the vagus was performed at Cadenat's Surgical Clinic in Paris. The effect of vagotomy on the secretion of gastric juice is limited to the initial phase of hydrochloric acid secretion (psychic phase). The insulin test is essential to determine the complete or incomplete character of the vagotomy but does not offer a complete picture of the effect of vagotomy on the secretion of gastric juice; the duration and importance of these effects have not yet been fully elucidated. The secretion of the vagotomized stomach may be modified by the administration of urethane of beta-methylcholine or carbaminoylcholine chloride. The latter may partially restore the motility of the stomach without reestablishing the secretion at its preoperative level, for which a triple dose would be required, and without jeopardizing or delaying the cicatrization of the ulcer. Vagotomy does not abolish hunger. No tendency to spasm was observed after vagotomy at the cardiac or pyloric sphincters. Early roentgenographic examination of the gallbladder after a Boyden meal in 2 cases of vagotomy showed that the gallbladder was evacuated within twenty to forty minutes, in 3 cases, six to nine months after the vagotomy, a disturbance of the evacuation of the gallbladder was observed. Diarrhea occurred occasionally either immediately or six to ten months after the operative intervention. Vagotomy is recommended for recurrent duodenal ulcers that are refractory to conservative treatment but not of the bleeding or stenosing type. It will probably be the method of choice for jejunal ulcers occurring after gastrectomy.

Actual Problems of Pediatrician. E. Glanzmann. -p. 105.
*Penicillin Treatment for Hematogenic Osteomyelitis. P. Wilflingseder. -p 109.
Vegetative Cardiac Attacks of Jarisch-Bezold-Type. K. Polzer and W. Schober. -p. 114.
One Hundred Retropubic Prostatectomies. R. Uebelhör. -p. 117.

Penicillin in Hematogenous Osteomyelitis.—Wilflingseder treated 24 patients, 22 of whom were less than 15 years of age, 18 with acute hematogenous osteomyelitis and 6 with chronic osteomyelitis, by intramuscular administration of penicillin. In 9 additional cases of acute osteomyelitis, children were treated with sulfonamide drugs, blood transfusions and immobilization. Doses of 1,000,000 to 2,000,000 units of penicillin proved sufficient in children in whom treatment was initiated in the first days of the disease. Three million units and more were required when treatment with penicillin was started only in the second or third week of the disease. Penicillin treatment must be continued until the pus becomes sterile, the temperature has been restored to normal, and pain and swelling of joints and soft tissues have subsided. These results were obtained in a girl aged 6 years only when the daily dose of the drug was increased to 300,000 units. In patients with subperiosteal abscess local application of penicillin was carried out by plombage of the abscess with instillation of 100,000 to 200,000 units of the drug. Within twenty-four hours of the instillation the punctate was sterile and the pus itself exerted a bacteriostatic effect on the Staphylococcus aureus. In 17 of the 18 acute infections complete recovery occurred in the absence of sequestration or formation of fistula. Partial stiffness due to sequestration and involvement of the joint occurred only in 1 case in which the dosage of penicillin was too small (600,000 units). Death occurred in 2 of the 9 patients with acute forms of the disease treated with sulfonamide compounds; 3 patients recovered, and 4 had a chronic course with sequestration and formation of fistula. There was no recurrence for year in 4 of the 6 patients with chronic osteomyelitis treated with penicillin, and fistulas which had remained open for two to five years were closed. There was no improvement in 1 patient, and in another progressive osteomyelitis with sequestration in both lower extremities could not be controlled even with 3,000,000 units of penicillin.

Book Notices

Textbook of Embryology. By Harvey Ernest Jordan, M.A., Ph.D., Sc.D., Professor of Anatomy and Director of the Anatomical Laboratories, University of Virginia, Charlottesville, and James Ernest Kindred, M.A.; Ph.D., Professor of Anatomy, University of Virginia. Fifth edition. Cloth. Price, $7.50. Pp. 613, with 501 illustrations. D. Appleton-Century Co., Inc., 35 W. 32d St., New York 1, 1948.

This work has always been distinguished by its effective use of illustrations and its emphasis on histogenesis. Recent editions have added significant data from experimental embryology and a painstaking documentation. The latter means nothing to the medical student but is of value to the instructor who wishes to judge the evidence for himself.

It grows increasingly difficult to keep successive editions of a textbook up to date without increasing its bulk and adding to the already exorbitant cost to the student. The present work illustrates various such difficulties. Thus in the new discussion of the menstrual cycle the old homology (Aristotle, Heape, etc.) of proestrus bleeding with menstruation is retained, although this interpretation has been disproved by histologic and hormonal studies. The chapter on the age of human embryos is chaotic because of the inadequacy of our present knowledge as to the time of ovulation, its relation to conception and the great variability in the time that may elapse between the death of the embryo and its abortion. In view of our ignorance one wonders what the effect on the student is when he comes on a mathematical formula for determining the age of an embryo from its length, which is by no means constant for any stage of development.

The old germ layer dogma is carried over (page 46) from the first edition, at which time conclusive evidence as to the derivatives of the neural crest (mesectoderm) was already five years old. In this table we also read that the iridial musculature arises " possibly from the ectoderm." Actually the dilator is from its first appearance and throughout life the contractile part of the myoepithelial cells which compose the pars iridica retinae. Any good preparation of a suitable stage shows the sphincter arising from the pigmented retina.

Each new edition of this and other embryologies has more of the splendid illustrations from the Carnegie Contributions to Embryology. The best are all from the pen of James Didusch, checked by G. L. Streeter. It is surprising, then, to encounter the grossly incorrect figure of Dandy's embryo (page 329), together with his naive interpretation of its nervous system. Similarly the old His figures remain, although they were corrected in 1916 by Hochstetter, whose monographs are omitted from the bibliography. Other errors include calling the brachium pontis a " commissure" and stating that the " cervical" flexure marks the junction of brain and cord.

A and *B* of figures 285 and 287 are misleading, as they have been shown to be chance variations rather then evidences of early sex differences in the external genitalia. Another figure that needs to be replaced is the atrocious reproduction of the youngest Hertig-Rock ovum (fig. 61).

In view of the emphasis on hemopoesis one wonders that the Rh factor is not mentioned.

This book is too useful to be handicapped by errors and should have the outdated vestiges of early editions systematically deleted.

Studies on Carbohydrate and Fat Metabolism with Especial Reference to the Pigeon. By Oscar Riddle and Associates, Department of Genetics, Carnegie Institution of Washington. Carnegie Institution of Washington Publication 569. Paper. Price, $1.85. Pp. 128, with 1 illustration. The Institution, 1530 P St., Northwest, Washington 5, D. C., 1947.

The investigations reported in this volume were carried out in an attempt to determine which pituitary hormones regulate carbohydrate and fat metabolism. The immature pigeon was used in most of the experiments. In some cases doves, rabbits and rats were also used. The data are presented in numerous tables showing the influence of the various hypophysial hormones (supplemented at times by other hormones) on carbohydrate and fat metabolism. The influence of ablation of various endocrine glands was also observed. The results of this study support the view that, in pigeons, very few anterior pituitary hormone share significantly in the regulation of blood sugar, muscle and liver glycogen, liver fat and ketosis. Anterior pituitary control of these processes is exerted chiefly through corticotropin, prolactin and thyrotropin. Posterior lobe products exert relatively slight effects. Curves describing the level of blood lipid at all phases of the reproductive cycle were constructed for pigeons and doves.

Incidental to these investigations, the data brought to light certain interesting aspects of the physiology of the pigeon in which there was a decided difference from that of mammals. To quote a few instances Hypophysectomy in the pigeon is followed by an increase of liver glycogen, whereas in mammals it is followed by a decrease Birds survive higher doses of insulin The adult reproducing pigeon shows cyclic glycemias and lipemias associated with egg production, a phenomenon not noted in mammals. As Dr. Riddle states in closing, "Most of these differences can be neither satisfactorily interpreted nor discussed at present; they stand as challenges to further research."

Hearing Aids and Audiometers: Report of the Committee on Electro-Acoustics. W.G. Radley, C.B.E., B.Sc. Ph.D., Chairman. Medical Research Council Special Report Series No. 261. Paper. Price, 1s. 3d. Pp. 71, with 28 illustrations. His Majesty's Stationery Office, York House, Kingsway, London, W. C. 2, 1947.

This pamphlet is a study of hearing in connection with the socialized medical program of the British Ministry of Health, comprised largely of scientific information which is in part a review of the literature of both the United Stated and Britain and in part original work done by the Committee on Electro-Acoustics. The committee has two principal tasks assigned: (1) to determine the practicability of designing a single type of electrically operated hearing aid which would be small, light, reasonably cheap to produce and service, and capable of giving good intelligibility of the spoken word to the majority of persons with deafness of types that can be benefited by mechanical appliances; (2) to determine satisfactory performance specifications for pure tone audiometers for use in the early diagnosis and accurate assessment of deafness of different types. The pamphlet is of major interest to the otologist and gives a good account of what is being done in England to assist those who are hard of hearing.

Applied Medical Bacteriology. By Max S. Marshall, Ph.D. With the collaboration of Janet B. Gunnison, M.A., Alfred S. Lazarus, Ph.D., Elizabeth L. Morrison, M.A., and Marian C. Shevky, A.B., Division of Bacteriology, Medical Center of the University of California, San Francisco. Fakrikoid. Price, $4.50. Pp. 340, with 10 illustrations. Lea & Febiger, 600 S. Washington Square, Philadelphia 6, 1947.

This book includes fourteen chapters. The first five are concerned with microscopy, sterilization and disinfection, glassware, culture mediums and cultivation, isolation and general technic. Other chapters are devoted to the use of laboratory animals, serologic technic, viruses, yeasts and molds, sanitation, biologic products, specimens and classification. Finally, the last chapter, occupying one hundred and sixty pages, is entitled "Diseases." Under this chapter some sixty-seven diseases are discussed, and for each disease a brief clinical description and the causative agent are given followed by a discussion of the specimens to be taken, the laboratory procedures to be followed and the significant laboratory data to be included in reports. The material is well organized and the tables and illustrations are well chosen. This book should prove helpful to clinicians, public health workers and sanitary inspectors as well as students and laboratory technicians in medical bacteriology.

Anatomy and Physiology Laboratory Manual and Study Guide. By Barry Griffith King, Ph.D., Commander H(S), U.S.N.R. Naval Medical Research Institute, National Naval Medical Center, Bethesda, Md., and Helen Maria Roser, B.A., M.A., R.N., Assistant Executive Secretary, American Nurses Association Professional Counselling & Placement Service, Inc. Section on Endocrines rewritten by Erwin P. Vollmer, Ph.D., Lieutenant H(S) U.S.N.R Naval Medical Research Institute, National Naval Medical Center, Bethesda, Md. Third edition. Cloth. Price, $3. Pp. 267, with 61 illustrations by M. Cartwright Baker. W.B. Saunders Co., W. Washington Sq. Philadelphia 5, 1948.

As the name implies, this book is a laboratory manual and syllabus. As such, it is beautifully illustrated with original drawings and tables which are well adapted for the class of students for which the manual was intended. The fact that it has now gone into the third edition indicates a degree of popularity which cannot be disregarded. It is elementary, to be sure, but evidently well suited to the class of students using it. It can be well recommended to any one interested.

Pharmacology and Experimental Therapeutics: A Survey for 1941-1946. By Hamilton H. Anderson, Fumiko Murayama and Benedict E. Abreu. Cloth. Price, $6 50. Pp 368, University of California Press, Berkeley 4, 1947.

The title of this book is somewhat misleading. The subject matter consists of brief abstracts of toxicologic and therapeutic information gleaned from the medical literature published during and subsequent to World War II. The drugs are arranged alphabetically, and only those which were subject to investigation during the period covered by the survey are included. Fortunately many of the older drugs were reinvestigated during the war years, and thus the volume contains information not only on the new synthetic chemicals but on many of the well known older agents.

This book is useful only when consulted in conjunction with other reference works on pharmacology and therapeutics. It may be considered as an appendix to the more extensive standard works, and as such will provide up-to-date information on recent investigations on drugs. The emphasis has been placed on quantitative toxicologic data, although metabolic and pharmacodynamic effects of the various drugs are mentioned. No attempt is made to review in a critical fashion the literature from which the data are derived.

As a supplemental reference work for pharmacologists and scientists in allied fields, this book will have some value. It is too incomplete and restricted in scope to be of interest to the practicing physician.

Caesarean Section: The History and Development of the Operation from Earliest Times. By J.H. Young, M.B., Ch.B., D.T.M. & H. With a foreword by Miles H. Phillips, M.D., B.S., F.R.C.S. Cloth. Price 16s. Pp. 254. H.K. Lewis & Co., Ltd., 136 Gower St., London, W.C.1., 1944.

This monograph on the history and development of the operation of cesarean section was originally written as a thesis for an M.D. degree at the University of Edinburgh. Professor Miles persuaded Dr. Young to enlarge it and to publish the manuscript in book form. The result is a complete story of abdominal delivery beginning in antiquity and extending to the present. A thorough search of the literature failed to discover the exact origin of the operation. The authentic history of cesarean section is divided into three periods; prior to 1500, from 1500 to 1876 and from 1876 to the present time. Prior to 1500 abdominal delivery was seldom performed and then solely for the postmortem delivery of the living child. From 1500 to 1876 sporadic operations were reported, chiefly on the continent of Europe, but recoveries were so few that the procedure was not recognized by the profession at large. The development of cesarean hysterectomy by Porro and its adoption by Sanger heralded the beginning of modern technic. However, abdominal delivery is largely a development of the twentieth century, for its successful use had to await the discoveries of antisepsis, anesthesia and the surgical skills.

The book includes chapters on the historical development of the variations of abdominal delivery as well as the surgical technic and the indications for the operation. The history of postmortem cesarean section is discussed. Finally, a short chapter is devoted to the religious and legal implications of sterilization procedures at abdominal delivery. An exhaustive bibliography is available at the end of each chapter. This historical document of one of the major procedures in obstetrics is interesting reading and will be enjoyed by obstetricians as well as by those who are students of medical history.

Kurze Klinik der Ohren-, Nasen-, und Halskrankheiten. Von Dr. Erhard Lüscher, ordentlicher Professor der Ohren-, Nasen- und Halsheilkunde und Direktor der Universitätsklinik und poliklinik fur Ohren-, Nasen- und Halskranke in Basel, Switzerland. Cloth. Price, 54 Swiss francs. Pp 513, with 201 illustrations. Grune & Stratton, Inc., 381 4th Ave., New York 16; Beno Schwabe & Co., Klosterberg 27, Basel 10, 1948.

A short clinic on diseases of the ear, nose and throat by Erhard Luscher appears to be the first postwar compendium in German. In his attempt to present a practical manual for students and general practitioners the author has unquestionably succeeded. Since the work was not primarily intended for the otolaryngologist, it will have no more than an academic interest to the specialist in this field. The entire subject matter, including bronchoesophagology, is well classified. Beginning with a brief descriptive anatomic review which is well illustrated by two hundred and one partly colored and exceptionally detailed drawings, the author proceeds to give a comprehensive presentation of the physiology of organs in this field.

Following a brief discussion of the instrumentarium required for a thorough otorhinolaryngologic examination, the author devotes considerable space to important clinical pictures and procedures found and utilized in the practice of this specialty. Thus, in his discussion of an ear examination, he stresses the importance of the appearance of the membrana tympani and describes thoroughly the use and importance of the eustachian catheter. For completeness, as is to be expected, he includes a discussion on audiometry. In his presentation of diseases of the middle ear, he explains aero-otitis or barotrauma and discusses thoroughly the problem of early surgical intervention in acute otitis media and acute mastoiditis. It is his opinion that early intervention in such cases is to be condemned and that only absolute indications should prevail

On the diseases of the nose, nasal hemorrhage and fractures receive most of his attention. He proffers many specific prescriptions and methods of treatment but again ascribes considerable importance to anterior and posterior tamponades in cases of nasal hemorrhage. He considers rather extensively dermatoses of the external nose, allergy, hay fever and rhinitis. It is interesting that in his discussion of sinusitis he recommends suction in both acute and chronic phases of the disease but makes no mention of the Proetz treatment as such.

In the diseases of the throat, the tonsil and adenoid problem receives a detailed discussion the author advising the removal of these structures only by competent specialists. It was somewhat surprising to read that he considers a suspicion of tuberculosis of the neck glands as an indication for tonsillectomy. He also recommends early tonsillectomy in about six or eight days following acute peritonsillar abscess. In considering the the question of focal infection, he agrees with the French authors that approximately 60 per cent of the latent sepsis is due to focal infections in the tonsils and that since neither sulfonamide or penicillin therapy is able to sterilize the primary focus a tonsillectomy is indicated.

Besides the usual prescriptions for pharyngitis, the author recommends balneotherapy and gives a list of twenty-four hot and cold springs in Switzerland alone. He takes occasion here to issue a special warning to general practitioners not to attempt removal of foreign bodies and manual procedures in the throat, hypopharynx and esophagus particularly in babies, where such procedures may result in the aspiration of the object into the lung or in pushing it into the stomach

The diseases of the larynx found only a short discussion but, the illustrations were exceptional in their clarity and educational value. In small slowly growing, circumscribed carcinoma of the larynx the author is satisfied with a transthyroideal cordectomy. He claims good results with this procedure and cites the results of other European authors. He recommends this type of surgery particularly in those patients who use their voice professionally. He is in full agreement with those who advocate preoperative roentgen therapy in an attempt to reduce the size of the tumor. For those patients who require a total extripation, he strongly recommends preoperative treatment with fractional dosage of roentgen radiation. After a short description of the neurogenic and functional disturbances of the larynx, the book closes with an extremely interesting chart of the new and old nomenclature. The new nomenclature was in all probability adopted by an international forum known as the I.N.S. (Nomina Anatomica, 1935).

Medicine. Volume One: The Patient and His Disease. By A.E. Clark-Kennedy, M.D., F.R.C.P., Physician to the London Hospital and Dean of the Medical School. Cloth. Price, $6. Pp. 383. Williams & Wilkins Co., Mount Royal & Guilford Aves., Baltimore 2, 1947.

To the student accustomed to the dry routine presentation of the subject of medicine in the manner of the usual textbook, Dr. Clark-Kennedy's monograph will make both interesting and stimulating reading. This is definitely not a textbook in the ordinary sense but rather a manual of instruction on the art of the practice of medicine. The patient is presented as a whole individual as met in the hospital bed or office and discussed as an organism with body and mind, reacting to the sum of hereditary factors and environment. It teaches the approach to the patient and the method of thought that should be employed in the analysis of the patient's symptoms and signs. Volume I presents a concept of all branches of medicine in a philosophical as well as scientific manner, correlated in writing as the practitioner must do in his thought when faced with the patient and his problem. It is divided into six chapters, with titles consecutively as follows: body and mind, symptoms, symptoms and signs, heredity and environment, reactions of the body and mind, and the nature of disease. The book is definitely not for the beginner in medicine

Signs and Symptoms: Their Clinical Interpretation. Edited by Cyril Mitchell MacBryde, A.B., M.D., F.A.C.P., Assistant Professor of Clinical Medicine, Washington University School of Medicine, St. Louis. Cloth. Price $12. Pp. 439, with 86 illustrations. J. B. Lippincott Company, 227-231 S. 6th St., Philadelphia 5, 1947.

In this volume a number of competent practitioners present basic considerations in the diagnosis of disease, making altogether one of the most instructive books available for either specialists or general practitioners. The chapters are devoted to the taking of the history of the patient and the analysis of symptoms such as pain, headache, sore tongue and sore mouth, fever, unconsciousness, swelling, loss of motion cough and change of weight. Here in concentrated form is graduate education of high quality The illustrations are excellent and adequately supplement the text, as does a detailed index.

Liberia. By Charles Morrow Wilson. Cloth. Price, $3.75. Pp. 226 with illustrations. William Sloane Associates, Inc., 119 W. 57th St. New York 19, 1947.

The year 1947 marked the centennial of Liberia as a republic. This book is a history of the early colonization of the country, the establishment of a commonwealth and ultimately the republic. The country is situated near the African Gold Coast; it has a land area of approximately 45,000 square miles and an estimated population of 1,600,000. Ninety-five per cent of the people are members of indigenous tribes. Citizenship and property rights are restricted to peoples of African blood.

For many years the culture and economy of Liberia were similar to others of the dark continent. Little progress was noted until the Firestone Tire & Rubber Company began developing some of the natural resources and introduced Hevea plantations. These plantations were a potent supply source of natural rubber for America and Allied nations.

Of interest to those associated with medicine is the important role of modern medicine in the cultural and economic advancement of the country. Although medicine is touched on throughout the book, one chapter, "Liberia and Medicine," deals more specifically with medical problems. For years modern medicine was unknown. George W. Harley, M.D., medical missionary, founded and still directs an impressive clinic in the tribal countryside of Ganta. His work and the medical personnel and facilities available through Firestone have brought scientific care to many Liberians.

There are still areas where the native medicine man is the only practitioner available to treat the natives. In the language of the Mano tribe "Nye ke mi" means the person who makes medicine—the doctor. Whatever his tribe, he is an important person acting as priest, physician and philosopher—much as the modern medical doctor is to his patients in more advanced countries.

Illustrations of Regional Anatomy. By E. B. Jamieson, M.D. Section I; Central Nervous System; Section II: Head and Neck; Section III: Abdomen; Section IV: Pelvis; Section V: Thorax; Section VI: Upper Limb; Section VII: Lower Limb. Seventh edition. Paper. Price, Section I, $3.50; Section II, $4; Section III, $3; Section IV, $2.50; Section V, $2.50; Section VI, $3; Section VII, $3.50. Pp. 51, with 51 plates; 52-115, with 64 plates; 116-159, with 44 plates; 160-194, with 35 plates; 195-226, with 52 plates. Williams & Wilkins Co., Mt. Royal & Guilford Aves., Baltimore 2, 1947.

This set is basically a cumulative record of the author's own dissections and teaching efforts. Occasional minor flaws are observed; these are probably due to the progressive expansion of the scope of work and the constant improvement in the quality of the material presented. These flaws, which are observed in conjunction with some illustrations, do not involve anatomic facts. This series can be used to great advantage by the medical student as well as the practitioner. The material is presented in sufficient detail and clarity to be as helpful in the dissecting room as in the private medical library. The illustrations are good and are particularly striking in the volumes dealing with the thorax and abdomen. Another desirable feature is the fact that individual volumes can be purchased.

An Introduction to Gastro-Enterology: A Clinical Study of the Structure and Functions of the Human Alimentary Tube. By James Dunlop Lickley, M.D. Cloth. Price, $3. Pp. 143, with 21 illustrations. Williams and Wilkins Co., Mount Royal and Guilford Aves., Baltimore 2, 1947.

This is a rather ambitious title for such a small book. Probably because the writer was once a lecturer on applied anatomy the best part of the volume is on the anatomy of the digestive tract. There is a section on the physiology of the tract, another on the pathologic physiology and another on clinical applications. It would have been somewhat of a miracle if the author had been able to pack into the small space available a really adequate amount of information. Material also should have been right up to date and based more on research articles than on old textbooks. Actually the book is somewhat disappointing and one feels that the writer could have done much better.

Biochemistry for Medical Students. By William Veale Thorpe, M.A., Ph.D. Fourth edition. Cloth. Price, $5. Pp. 496, with 36 illustrations. Williams & Wilkins Co., Mount Royal and Guilford Aves., Baltimore 2, 1947.

This book, as its title implies, was written primarily for the use of medical students, and particular emphasis has been placed on problems of diagnosis. An effort has been made to supply facts and methods which the medical student should know about rather than to deal with theory. A bibliography supplying references to monographs and special articles is furnished for more detailed study. In the present edition (fourth) particular attention has been paid to the problem of the use of isotopes in biochemical investigations, and the sections on protein structure, coenzymes, flavoproteins, bile pigments and nutrition in wartime have been largely rewritten.

The general plan of the book is as follows: Following a preliminary discussion of physical-chemical principles there is discussion of substances found in tissues and food. This includes consideration of special catalysts. In part 2 problems of digestion and absorption and of intermed~~iary~~ metabolism are considered, as well as the role of hormones and vitamins in metabolism. Part 3 deals largely with problems of energy needs, food composition, nutritional aspects and waste products.

The small size of the book makes it easy to read, and its condensed form enables the student to learn many facts about biochemistry in an elementary way. It is unfortunate that the author expresses measurements of intestine in man in terms of feet, absorptive area in terms of square meters, and total weight in terms of stones. It is hoped, however, that in future editions the metric system will be utilized consistently.

Bovine Tuberculosis Including a Contrast with Human Tuberculosis. By John Francis, B.Sc., M.R.C.V.S. Fabrikoid. Price, 25s. Pp. 220, with 36 illustrations. Staples Press, Ltd., Staples House, 10 Cavendish Place, London, W.1, 1947.

This small volume presents rather well the subject of bovine tuberculosis. The author traces the disease from the Mediterranean littoral, particularly Rome, to Britain and Northern Europe. Finally, the infected high bred English cattle disseminated the disease to many other parts of the world.

No control was attempted until after the tubercle bacillus was found. Ostertag in Germany attempted, unsuccessfully, to wipe out the disease by killing off all the ill cattle. Bang, in Denmark, had more success by separating all calves from their mothers and starting new herds with the young animals. Since only 0.5 per cent of the young are infected at birth, this method was fairly successful. Another method, used mostly in England, was to do tuberculin tests in herds and regions and gradually separate the infected animals and eliminate them. Finally, the method used in the United States was to kill off all tuberculin reactors on a national scale. As a result, practically no tuberculosis remains in continental United States. The Federal Government, the state and the owner each bore an equal share of the loss.

Vaccination has been a total failure. BCG protection lasts only about six months, and the vaccine made from the human strain may be passed back to human beings.

The pathogenesis of the disease is considerably different from that in human beings. There is not the susceptibility in young cattle that there is in young human beings, and the complete healing of tuberculous lesions in cattle is a rarity. Reinfection lymph node complexes, rare in the human being, are the rule in cattle. Lymph nodes do not rupture into bronchi in cattle as they frequently do in human beings. Some breeds of cattle are more resistant than others. Herefords are more resistant than Jerseys, and the Zebu African cattle are the most resistant of all. About 5 per cent of tuberculous cows have metritis as a result of hematogenous dissemination, but only 1 per cent of the calves are infected. From 1 to 2 per cent of tuberculous cows have tuberculous mastitis also, as a result of hematogenous seeding. Cattle are infected generally by the aerogenous route (80 to 90 per cent) usually while in their stalls. Infection is rare in open pastures. Infection of man with bovine tubercle bacilli (where bovine bacilli are prevalent) is around 5 per cent, and about 30 per cent of tuberculous children have bovine infections due to drinking infected milk. Cattle are only slightly susceptible to avian and human strains of tubercle bacilli.

Some good photographs of typical bovine lesions, appropriate charts and tables and an easily readable type make the work a worthy addition to the literature of comparative medicine.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

CHRONIC HEPATITIS

To the Editor.--A 28 year old white female patient in March 1947 experienced headache, malaise, anorexia, moderate pain in the upper part of the abdomen and in the lumber region, nausea, vomiting and diarrhea. She ran a low grade fever. Physical examination revealed a palpable tender liver and moderate inguinal and cervical lymphadenopathy, as well as pharyngitis. Blood count and hemoglobin were normal; the blood Wassermann reaction was negative. The urine was dark brown, and the thymol turbidity test positive in result. The icterus index was 9; cephalin flocculation reaction was 4 plus, and the sulfobromophthalein sodium test normal in result. The patient was treated with rest in bed, a diet low in fat, infusions of 5 per cent glucose, vitamin B complex and sulfadiazine, 1 Gm. every four hours. After six weeks of rest in bed there was symptomatic improvement, but the cephalin flocculation reaction remained 2 plus. In August of 1947, while on vacation, the patient experienced severe diarrhea, and a Salmonella organism was cultured from the stool. After therapy with succinylsulfathiazole and sulfasuccidine the cultures became negative. However, at this time the patient again experienced pain in the right upper part of the abdomen, nausea, vomiting, headache and mild diarrhea persisted. Several tests showed a persistent 2 to 3 plus cephalin flocculation reaction, and normal sulfobromophthalein sodium reaction. The blood alkaline phosphatase and albumin globulin ratio were normal and the icterus index 6. The patient was put on rest in bed for three months and a diet high in protein and in methionine advised. Vitamin B complex and folic acid were prescribed. A course of dehydrocholic acid was given, 1 tablet three times a day. At the present time the patient is again at work, and on a regular diet with no medication. She has occasional severe headache and nausea, and persistent soreness in the hepatic region. The cephalin flocculation reaction remains at 2 plus, and sulfobromophthalein sodium reaction normal. Would a liver aspiration biopsy be advisable, or justified in this case? What value, or danger if any, is there in the use of sulfadiazine, folic acid and dehydrocholic acid in this case? What diagnostic procedures would be of value in following this case, and what therapeutic program is suggested? What is the prognosis?

M.D., New York.

ANSWER.—The history and findings in this case are consistent with those present in a diagnosis of infectious hepatitis, although the minimal degree of icterus places the case in the category of anicteric cases. Symptoms of the type described are oftener encountered in areas where the disease is epidemic than where it is sporadic, and one wonders whether this patient had any contact with other persons suffering from the disease or whether there is any history of antecedent use of blood or plasma. The complicating Salmonella infection is not unusual and is not necessarily connected with the relapse of hepatitis which the patient apparently had thereafter.

Residual malaise with pain and soreness in the region of the liver may indicate low grade chronic hepatitis. Such symptoms, however, may be of little clinical significance, since some degree of retention of sulfobromophthalein would be expected if the hepatitis were active. In regard to other tests of hepatic function in this patient, the only definite finding mentioned is the weakly positive result of the cephalin cholesterol flocculation test, which is hardly sufficient for diagnosis. The thymol turbidity test and the test for determination of serum bilirubin should be repeated; the level of serum globulin should be checked. If this exceeds 3.5 Gm. per hundred cubic centimeters of serum and there is thymol turbidity in excess of 4 units, the hepatitis may still be active. Cholesterol and esters should be checked, and, if possible, quantitative studies of the urobilinogen content of the urine should be performed. As Watson and others have shown, the hepatitis may still be active so long as there is significant urobilinogenuria, no matter what other tests of hepatic function may show. In such cases, an increased excretion of the type I isomer coproporphyrin in the urine may be a concomitant finding. If the liver is readily palpable below the costal margin, a needle biopsy may be justifiable; it is conceivable that it may give information of value. The reader is referred to a recent account of the residues of hepatitis by Kunkel, Labby and Hoagland (*Ann. Int. Med.* 27:202-219 [Aug.] 1947) for more detailed information in regard to diagnosis and classification of such cases.

Treatment of chronic or relapsing infectious hepatitis in the active phase is largely a matter of rest, a diet high in calories and in protein and elimination of existing infections elsewhere in the body. In the inactive phase, the maintenance of optimal nutrition is the only requirement (Capps, R. B., and Barker, M. H.: *Ann. Int. Med.* 26:405-416 [Mar.] 1947). No benefit will accrue from the use of the sulfonamide drugs, bile salts or folic acid so far as is now known; the first two remedies may, at least in some cases, do harm. The prognosis is probably good, although the ultimate developments in chronic hepatitis are still not clearly understood.

MENOPAUSE AND FERTILITY

To the Editor:—Is there any examination acceptable to the courts in determining whether it is possible for a woman, age 56, who has passed the menopause, to bear children?

J. P. Richardson, M.D., Ellensburg, Wash.

ANSWER.—Fertility in women reaches a low ebb in the premenopausal period and is completely extinguished after the menopause. There is no likelihood of pregnancy when menses have been absent for a year. It is of interest that the oldest woman to give birth to a baby in 100,000 consecutive deliveries was 46 years old and the oldest pregnant woman was 48.

The following findings are typical of the postmenopausal period and indicative of a complete absence of fertility. Their presence in a 56 year old woman should bear considerable legal weight: 1. Atrophic changes in the external genitalia, the vagina and the uterus become increasingly evident during the postmenopausal period. 2. Endometrial biopsies reveal atrophy of the endometrium which is fairly characteristic. 3. There is a great decrease in urinary estrogens although traces of such hormones are detectable for several years after the cessation of the menses. 4. The onset of the menopause is associated with a greatly increased elimination of urinary gonadotropins (ten to fifty times the normal amount), follicle stimulating in character. 5. Only traces of pregnandiol are present in the urine, and these ultimately disappear.

CONTAMINATED WELLS

To the Editor:—For the past five months my neighbor and I have noticed an odor of gasoline in our water supply. It varies from a slightly perceptible to a disagreeably strong odor, although at no time has the water been discolored or covered with an oily film. Both our houses are supplied by driven wells 60 to 75 feet (18.3 to 22.9 meters) deep, with an outer casing of iron pipe at least 40 feet (12.2 meters) deep, and the lead-in pipe from the well to the house is completely cemented into the casing. Both wells are within 6 feet (1.8 meters) of the houses. There are four gasoline stations in the immediate vicinity, each with underground tanks of over 500 gallon (1,890 liter) capacity. The distances are 90 feet (27.4 meters), 75 feet (22.9 meters), 250 feet (76.2 meters), and 100 feet (30.5 meters), respectively. Air pressure tests on the nearest tank revealed no leak. The other tanks were measured by stick; that is, the level of the gasoline in the tank was noted on a stick and checked after twelve to eighteen hours. Leakage was not noted with this method, which is admittedly inaccurate. The owners, however, would not or could not use the air pressure method. On opening the casing cover on one well, the odor of gasoline was distinct and a lighted match dropped in caused a flash fire. The ground was dug up for about 5 feet (1.5 meters) around this well to get to the casing, and this ground also had the odor and burned when ignited. A sample was obtained from the surface of the well, and it was a dark black oily liquid smelling strongly of gasoline. It is known that at the site of the tank 250 feet away about fifteen to eighteen years ago about 10,000 gallons (37,850 liters) of gasoline was lost through a leak in the tank that was put in underground. I have several questions on the problem: 1. Is this contaminated water harmful for drinking, cooking or washing? 2. Since each tank is owned by a different company, can chemical analysis identify different brands of gasoline? 3. Could the gasoline lost years ago be the cause of our present contamination? 4. Would digging deeper wells help us in obtaining a clean water supply? 5. Is there a filter on the market that would be of help to us?

Abraham D. Cohen, M.D., New City, N.Y.

ANSWER.—1. There is danger of lead contamination of the drinking and culinary water, as most modern motor fuels are leaded. The United States Public Health Service considers waters having lead content in excess of 0.1 part per million as unacceptable for drinking purposes. Obviously the water may be used for washing if the gasoline odor is not too objectionable. Fire and explosion hazard should be considered in the use of the wells if, as stated, the gasoline vapors in one of the wells has been ignited.

2. It is doubtful whether chemical analyses will indicate the source of the gasoline pollution unless the fuels from the various storage tanks are of distinctly different grades.

3. The gasoline which leaked into the ground years ago may be causing the contamination, but if so it is difficult to understand why it did not show up in the wells prior to five months ago. More recent gasoline spills should be considered as possible sources of pollution.

4. Drilling of deeper wells to tap lower water-bearing strata may be the solution of the problem. The well casings should be sealed to prevent entrance of the gasoline-contaminated water from near the surface of the ground. The local well drillers should be able to advise regarding the availability and quality of water from deeper strata and regarding the practicability of sealing off water from strata near the ground surface.

5. Gasoline odors can be removed by filtering the water through activated carbon if the water is not seriously contaminated. Such filters are available on the market. They will not remove lead from the water.

RADIOACTIVE IODINE

To the Editor:—In the Feb. 22, 1948 issue of the *American Weekly* is an article entitled "Atomic Energy, World's Greatest Killer of Toxic Goiter" by G. B. Lal. The atomic drink—colorless, odorless, tasteless; the dose, usually small, of radioactive iodine cured the patient. Just what is the status of radioactive iodine?

William J. Stapleton, M. D., Detroit.

ANSWER—There are still not enough observations to say definitely what the status of radioactive iodine is in the treatment of toxic goiter. From data available it appears possible to produce a cure in a relatively large percentage of patients. If the correct amount of radioactive iodine is given, one dose is usually adequate. It has the advantage that it may be given by mouth. Thyroxin, which is the most important constituent of the thyroid hormone, contains 65 per cent of iodine by weight. When iodine is given in small quantities, it is taken up almost entirely by the thyroid, and if it is radioactive it destroys the thyroid cells. Patients who have received this form of treatment have not yet been followed long enough to determine whether there are any late complications, notably carcinoma. Expensive apparatus is necessary to follow the effect of radioactive iodine in an intelligent manner. Because of the expense involved and the uncertainty concerning complications of treatment, the use of radioactive iodine has been restricted to those patients who present poor operative risks. Propylthiouracil has been used for medical management in the same types of patients.

PETIT MAL

To the Editor:—During the past several months I have had under my care a middle-aged, white bipara who has had recurrent attacks of petit mal. Trimethadione ("tridione") with phenobarbital decreased the attacks for approximately three weeks, but the attacks then recurred, and the patient's leukocyte count approached 4,500 per cubic millimeter; hence the trimethadione was discontinued. She is now on 4 to 6 Gm. of glutamic acid daily with phenobarbital. Do you have any further suggestions?

M.D., California

ANSWER.—Petit mal (pyknoepilepsy) is rare in persons of middle age. The attacks are easily confused with mild psychomotor seizures. If possible, the diagnosis should be checked by the electroencephalograph. Psychomotor seizures require from 0.3 to 0.5 Gm. of diphenylhydantoin sodium or of "mesantoin" (methylphenylethyl hydantoin) (or of both). If the attacks are petit mal, a larger dose of trimethadione than that given may be required. Neutropenia (1,600 white cells per cubic millimeter or lower) or sharp reduction in the abundance of platelets calls for discontinuance.

LEUKOPLAKIA

To the Editor:—There is a difference of opinion among the physicians at this hospital as to the best method of treating leukoplakia of the lower lip. Some favor radiation therapy, while others recommend peeling of the lesion followed by cauterization of the base. I would appreciate an opinion.

C. K. Pearlman, M.D., Huntington, W. Va.

ANSWER.--Leukoplakia of the lower lip only is commonly induced by the irritation from pipe smoking. There is no specific cure. The treatment of leukoplakia divides itself into preventive and active measures. One should remove the known common causes. These include poor oral hygiene, such as poor dental alinement, accumulation of tartar and decay. Dentures must fit properly and be clean. Strong drinks and irritating foods that are too hot and highly spiced are agents which predispose to and aggravate the condition. Smoking is the commonest agent known to induce and continue leukoplakic changes of the mouth. An important part of any treatment regimen must depend on the complete interdiction of this habit. Most observers agree that half-hearted measures to discontinue the use of tobacco led to failure. The physician should be the patient's prop in the early trying days. He must be sympathetic and yet induce courage by his forcefulness. The complete cessation of smoking leads often to surprisingly gratifying results. Simple mouth washes as with sodium perborate solution are useful.

Leukoplakia sometimes involutes or improves with the administration of vitamin A. The dose is from 50,000 to 150,000 units a day and should be continued for an extended period. Estrogenic substance is said to be of benefit, but this statement lacks sufficient verification. Use of estrogens should be attended with the caution that hormonal therapy in general deserves. Caustic agents such as silver nitrate are to be avoided. They are not curative but frequently produce damage. Cancer can supervene from their use. If a destructive method is desirable, this is best found in the use of actual cautery, electrocoagulation, fulguration or surgery.

Syphilis is said to be a sufficiently frequent factor in the production of leukoplakia to warrant careful search for its possible presence. Some consider that antisyphilitic therapy is warranted even though the results of blood serum tests and physical examinations are negative. It would seem, however, that there should be some definite support for such an attack above mere surmise.

Where the changes in the mucous membrane are smooth and the surface is intact with no tendency to bleed, conservative measures are apt to suffice and sometimes cure. Otherwise, active measures become necessary. It must be remembered that squamous cell cancer may be an end result in the thickened, fissured and bleeding forms of leukoplakia and calls for the radical measures appropriate for it. Radiation therapy is used by some, but effective doses are cauterizing. The majority of observers do not favor its use except in connection with cancerous degeneration.

ELECTROCARDIOGRAPHY

To the Editor:—Appreciating that theoretically unipolar electrocardiography is superior to bipolar or standard studies, can it be expected that the former will generally replace the latter? Other than for correlative study is there a sound reason for routinely recording both standard and unipolar limb leads? Are most progressive cardiac clinics and medical services employing unipolar studies at present?

Felix Wroblewski, M.D., Brooklyn.

ANSWER.—The present controversy about unipolar leads does not concern the desirability of using true unipolar leads. All authorities agree that a truly unipolar lead is highly desirable. At present there is considerable argument over the present technic of taking unipolar leads. One school of thought led by Wilson maintains that the central terminal used for taking these leads has a potential close enough to zero to permit the recording of leads which are for all practical purposes unipolar. The opposing school of thought led by Wolferth maintains that the central terminal is not of zero potential and that the leads recorded are not true unipolar leads. This problem has not been settled and until it is unipolar leads will not replace bipolar leads. When it becomes possible to prove that electrocardiographic leads can be made unipolar, bipolar leads will become entirely superfluous. Until that time many electrocardiographers are using the so-called unipolar leads in order to gain experience with them.

It is not within the scope of this communication to list the advantages of unipolar leads, nor can the question about the progressiveness of clinics using these methods be answered.

SULFAMERAZINE

To the Editor:—Kindly supply information on rashes following medication with sulfamerazine; data in relation to method of administration; dosage, and possible toxic effects.

M.D., Pennsylvania

ANSWER.—Many of the rashes attributable to other sulfonamide compounds have followed the administration of sulfamerazine. These rashes include generalized erythema, maculopapular eruptions, purpura, erythema multiforme, erythema nodosum-like lesions and, rarely, an exfoliative type of dermatitis. In one large clinic the incidence of rashes with sulfamerazine was no greater than that associated with sulfadiazine and less than that following the administration of sulfathiazole.

For systemic bacterial infections the oral dose of sulfamerazine for small children is ½ to 1 grain (0.0325 to 0.065 Gm.) per pound of body weight in twenty-four hours. For adults an initial oral dose of 3 to 4 Gm. is followed by 1 Gm. every six hours. The sodium salt of sulfamerazine may be utilized for intravenous administration. It is desirable that the patient maintain an alkaline urine while sulfamerazine is being administered, and for this purpose sodium bicarbonate may be employed in a total daily amount of 12 to 14 Gm. given in divided doses. The total output of urine should be observed closely.

The toxic effects of sulfamerazine are similar to those encountered with sulfadiazine and other sulfonamide drugs and include renal complications such as hematuria, oliguria, pain and anuria. This last [illegible] complication can be prevented to some exte[illegible]f the urine and the administration of adequate fluids. Blood dyscrasias such as granulopenia and agranulocytosis occur rarely, usually after the drug has been administered for two or more weeks. Rashes may appear but subside shortly after the discontinuation of therapy. Febrile episodes may indicate toxicity.

Sulfamerazine has about the same therapeutic advantage as sulfadiazine and is no more toxic than the latter. Blood concentration of sulfamerazine are maintained for longer periods than those which are obtained with equivalent doses of sulfadiazine. This indicates that sulfamerazine can be given at less frequent intervals, which is a distinct therapeutic advantage, especially in children.

NEUROLOGIC SYMPTOMS FOLLOWING INJECTION OF MERCURIAL

To the Editor:—Following up the discussion of the subject "Neurologic Symptoms Following Injection of Mercurial" (THE JOURNAL, Oct. 11, 1947, p. 396) and Dr. A.H. Ulm's note (February 7, 1948, p. 434) in Queries and Minor Notes, it has been my observation in many older, hypertensive arteriosclerotic persons that the symptoms of numbness, tingling and especially the cramping of the posterior lower leg muscles will occur if the dose of the mercurial compound is too large. I tried to explain this to myself on the hydrodynamic theory, because it only happened a number of hours after the administration of the mercurial and only after adequate diuresis or more than adequate diuresis. The pain is similar to the muscle cramp of intermittent claudication but will occur at rest also, and all the sooner if the patient is on his feet and walking. I have never had this complaint from a female patient. Physicians had all better learn that an ampule's content of 2 cc. does not mean that the dose is 2 cc. Does one administer the full 1 cc. of epinephrine in an attack of bronchial asthma just because the ampule contains 1 cc.?

Robert R. Schwartz, M.D., Bronx, N.Y.

MEDICATION FOR PINWORM DURING PREGNANCY

To the Editor:—The answer in THE JOURNAL, Feb. 7, 1948 page 434, on the subject "Medication for Pinworm during Pregnancy" is incomplete. The most efficient drug for eradication of pinworms is gentian violet tablets with water-soluble coating. The adult dose is 1 grain (60 mg.) three times a day one hour before meals for eight days, followed by a seven day rest period. The treatment is then resumed for another eight day cycle. For children 15 or under, the schedule is the same with a dose of 10 mg. of gentian violet per day per year of age. Hexylresorcinal is also effective but in a much larger dose than recommended in the aforementioned article. For an adult, the contents of one vial, a total of 1 Gm. of the drug, are taken at one time, to be repeated in a week if needed. Enemas of 1:1,000 hexylresorcinol, approximately a quart being used at a time, are also beneficial. Frequent repetitions of therapy are often required, since reinfestation is rather common.

ROENTGEN EXAMINATION OF THE STOMACH IN SYMPTOMLESS PERSONS

LEO G. RIGLER, M.D.
Minneapolis

Despite the enormous effort that has been expended on the surgical approach to carcinoma of the stomach and on better methods of diagnosis the results in this disease are still exceedingly poor. Of all the tumors, cancer of the stomach continues to produce by far the largest number of deaths. The vast majority of persons coming to surgical treatment, even at the present time, are in an advanced stage of the disease, so much so that surgical treatment is impossible in a high percentage of the cases. In order that there be any opportunity for a surgical cure in carcinoma of the stomach the diagnosis must be made at a sufficiently early stage so that extirpation is feasible and metastasis to lymph nodes is not yet present. Some means must be devised to discover carcinoma of the stomach when the lesion is small and in an early stage of development.

Because of the insidious onset and the relatively late development of symptoms, tumors of the stomach are frequently of large size before they are recognized. It is more and more evident from various studies that have been made that surgical cures of carcinoma of the stomach will continue to be infrequent unless the diagnosis is made before the development of any appreciable symptoms or physical signs. From studies which my associates and I have pursued over a period of years it is evident that a tumor of the stomach may attain a remarkably large size at a time when the patient denies any appreciable gastric disturbance. While it is true that relatively small tumors occasionally produce symptoms, such an event is the exception, not the rule. It is trite to say that a skin test for carcinoma or some blood test which would be suggestive of the presence of carcinoma would be highly desirable as a means of selecting cases for further examination; no doubt such a procedure would constitute a simple and effective method for the early detection of carcinoma of the stomach. Unfortunately, no such process is presently available and, therefore, in the light of present knowledge, some other method must be considered.

It is true that gastroscopy might conceivably be practiced on a large scale and by this means some cases of carcinoma of the stomach might be detected at an early stage. All of our experience and that of many others indicates that this is not practical; it is difficult to persuade patients to submit to gastroscopy unless there is a specific and serious indication. Furthermore, the diagnostic accuracy of gastroscopy is sharply limited by reason of the inability of the gastroscopist to visualize certain portions of the stomach and by the difficulties dependent on the passage of the gastroscope in certain elderly persons. There are other intrinsic limitations of the method.

Even the most careful study of the history and physical signs is, as has been stated, an ineffective means for the detection of gastric cancer, since it usually gives no information until the tumor is well advanced. It has been pointed out that the universal employment of roentgen examination of the stomach in persons with gastric symptoms would result in the detection of a much larger number of operable carcinomas than is presently the case. Nevertheless, for the long range pursuit of the reduction in mortality in carcinoma of the stomach, some other procedure must be undertaken by which the tumors will be discovered before the development of any symptoms or physical signs.

In the absence of any other means the only method which appears to be universally applicable and reasonably accurate is the routine roentgen examination of the stomach. Such studies have been proposed on a number of occasions and have been undertaken in certain selected groups. Because the incidence of carcinoma of the stomach is relatively low, probably not more than 3 per thousand of the living population over the age of 45, the productivity of routine roentgen examination is of such an order as to discourage efforts to undertake it. Nevertheless if any real impact on the problem of carcinoma of the stomach is to be made within the limits of present knowledge of diagnosis and treatment some efforts must be exerted in this direction.

Mass diagnostic surveys of the population using the roentgen method have been reasonably effective in the discovery of diseases of the lungs. In large part this effectiveness is due to the relative ease and inexpensive character of the roentgen examination of the thorax. Unfortunately such ease of procedure and lack of expense do not apply generally to the roentgen examination of the stomach. For this reason serious questions have arisen as to whether this type of examination can be applied generally to large sections of the population who are relatively symptomless.

ACCURACY OF ROENTGEN METHOD

The first question which must be answered is whether or not the roentgen method is actually an accurate procedure for the diagnosis of carcinoma of the stom-

---

From the Department of Radiology and Physical Therapy, University of Minnesota.

Read before the Section on Radiology at the Ninety-Sixth Annual Session of the American Medical Association, Atlantic City, N.J., June 11, 1947.

ach. Various statistical studies have been published in past years bearing on the accuracy of roentgen examination and indicating that it is an extraordinarily reliable procedure. The published data, however, are based almost entirely on symptom-producing tumors, the vast majority of which are of large size and readily detected. There are a few reports in the literature indicating the possibility of roentgen diagnosis of really small carcinomas of the stomach. There are, in addition, some reports of small benign tumors of the stomach, but in comparison to the extremely large number on which statistical studies are based these are extremely uncommon.

Some experience has already been had in the demonstration of tumors of the stomach in symptomless persons. In a report [1] on patients with pernicious anemia, examined at semiannual intervals over a considerable period of years, my associates and I have demonstrated that it is possible to make the diagnosis of extremely small benign polypi in the stomach, some as small as 5 mm. (fig. 1) in diameter, and that relatively small carcinomas can also be demonstrated by the roentgen method. In a previous report [2] made much earlier I detailed some cases of carcinoma of the stomach of not more than 1 cm. in size which were successfully diagnosed by roentgen examination of the stomach.

In a second series, a group of symptomless persons, whose only indication for roentgen study was achlorhydria, were examined and a similar experience was obtained. In the course of these studies, however, it has become clearly evident that when small lesions are being searched for the percentage of error will rise appreciably and that positive errors will likewise be increased in their frequency. The effort to interpret small changes of significance in persons without symptoms may readily lead to a false positive diagnosis which might otherwise not have been made. At the same time extremely small lesions may easily escape detection.

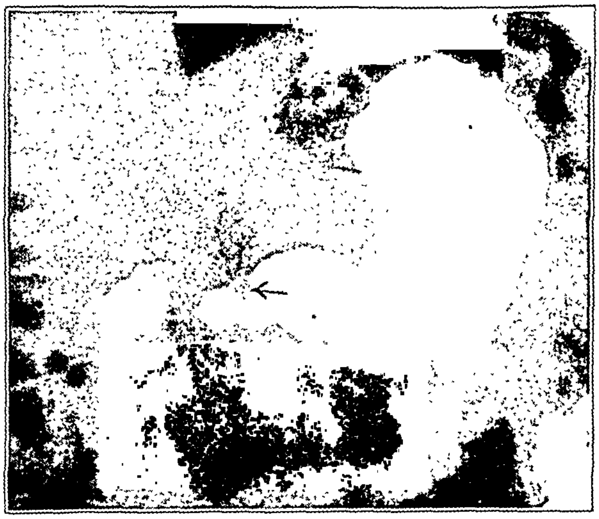

Fig. 1.—Benign polyp in antrum of stomach in a patient with pernicious anemia and no gastric symptoms. Conventional roentgenogram, right anterior oblique supine position. Note small, rounded, sharply defined filling defect (arrow). The lesion was found on routine roentgen examination. Gastroscopically, there was some suggestion that it might be malignant. Gastric resection was done. The tumor measured 5 mm. in diameter and was histologically benign.

In the practical consideration of the feasibility of extensive routine examinations of symptomless persons certain short cuts should be considered. It may be possible to reduce the number to be examined, and thus increase the productivity of the procedure, by selecting persons from the general population on the basis of some easily determined associated finding. The examination itself might be facilitated and rendered less expensive by changes in technic.

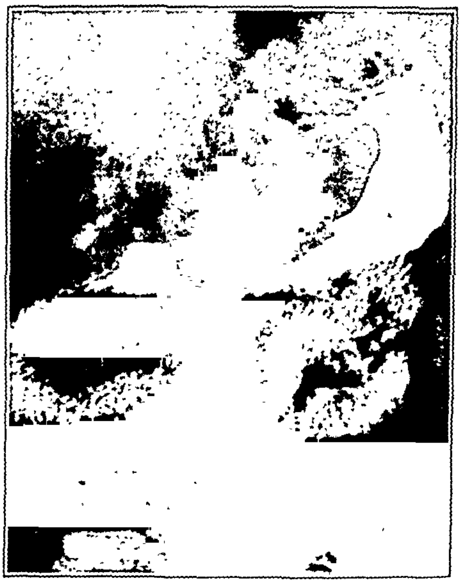

Fig. 2.—Carcinoma on lesser curvature of stomach in a patient with pernicious anemia and no gastric symptoms. Conventional posteroanterior roentgenogram, prone position. Note small, irregular, shallow filling defect with overhanging edges (arrow), measuring about 1 cm. in diameter. There is a suggestion of a small area of ulceration in the center. The lesion was not observed on the first fluoroscopic examination and was discovered as a result of the routine use of conventional roentgenograms. The patient refused operation but returned a year later with definite symptoms. The growth was then much more extensive and the surgeon was unable to remove all the carcinoma.

METHODS OF SELECTING PERSONS FOR EXAMINATION

In the effort to accomplish an effective selection of persons in whom the incidence of carcinoma would be greater than in the general population, certain conditions which seem to be associated with or to precede carcinoma of the stomach should be discussed.

The following are some of the common factors which accompany or precede carcinoma of the stomach and which might be used to select cases for further study.

1. *Age.*—Since the incidence rises sharply at the age of 50 examination of all persons beyond this age could be used. The number of persons to be examined would be extremely large and the productivity would be extremely small, as has been indicated, but a selection on this basis is absolutely necessary if the procedure is to have any chance of success.

2. *Family History of Carcinoma of the Stomach, Pernicious Anemia or Achlorhydria.*—It is thought that persons from families with a history of carcinoma of the stomach, pernicious anemia or achlorhydria are more likely to have gastric cancer than the rest of the population. While such data are of interest from the standpoint of etiology they are of little value from a practical point of view in order to discover cases, since the associated incidence is extremely small.

[2] Rigler, L. G.: The Roentgen Diagnosis of Small Carcinomata of the Stomach, Wisconsin M. J. **34:** 236, 1935.

3. *Atrophic Gastric Mucosa.*—Atrophic gastric mucosa is undoubtedly related to the development of some cancers of the stomach and of many benign epithelial tumors. There are, however, no specific indications for the presence of this process and it can scarcely be discovered except by gastroscopy, which, as has been pointed out, would not be a feasible routine procedure.

4. *Gastric Ulcer.*—Gastric ulcer may possibly be related to carcinoma in an extremely small number of cases. Certainly all cases of gastric ulcer should be looked on with suspicion and followed by repeated examination. Nevertheless, only a few carcinomas of the stomach will be discovered in this manner.

5. *Occult Blood in the Stool.*—Occult blood in the stool is frequently found in carcinoma of the stomach and may be a helpful accessory means of finding patients who may have a tumor. The application is limited, however, and would obviously only result in the discovery of a portion of the cases. As a practical matter it is difficult to apply.

6. *Achlorhydria and Hypochlorhydria.*—The absence of free hydrochloric acid in the gastric contents, especially if the analysis is made after the triple histamine test, is a common accompaniment of gastric cancer. It is probable that almost 90 per cent of all the cases of carcinoma of the stomach will exhibit less than 30 units of free hydrochloric acid in the gastric contents if the triple histamine test is used (Hebbel and Gaviser[3]). By a gastric analysis for all persons past the age of 50, followed by roentgen examination for all those with values as indicated, the vast majority of carcinomas could be discovered. Furthermore, this would reduce the number of persons to approximately 30 per cent of the age group, an enormous saving in time and effort. This proposal has already been made by Wangensteen[4] and a preliminary report of the studies has been made by State.[5] The results of the roentgen study in such cases will be discussed later.

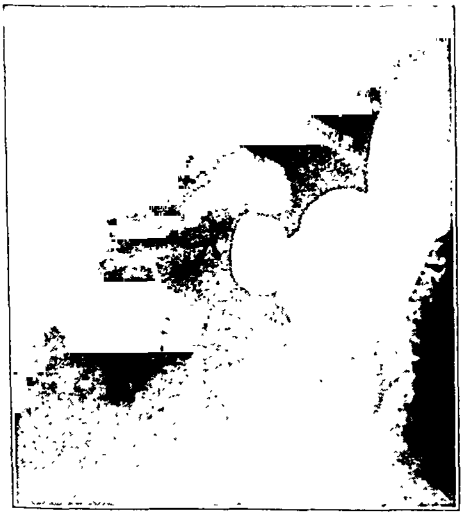

Fig. 3.—Carcinoma at pylorus, greater curvature, in a patient with achlorhydria and no gastric symptoms. Conventional roentgenogram, right oblique anterior supine position. Note rounded defect in base of duodenal bulb and on greater curvature of pylorus (arrow). The lesion was missed both on fluoroscopy and in the examination of the roentgenograms. It was an error of interpretation and indicates the difficulty of roentgen diagnosis of certain small lesions. The patient had a carcinoma of the cecum for which he was operated on, and a small carcinoma measuring about 2 cm. in diameter was found on the posterior wall of the pylorus extending outward and compressing the duodenum.

7. *Pernicious Anemia.*—The close association of pernicious anemia with carcinoma of the stomach has been clearly established by previous studies.[6] Repeated examination at semiannual intervals of patients with pernicious anemia has resulted in the detection of a considerable number of early cancers of the stomach. As a practical matter, however, it does not approach a solution of the problem, since only 5 per cent of persons with carcinomas of the stomach have pernicious anemia.

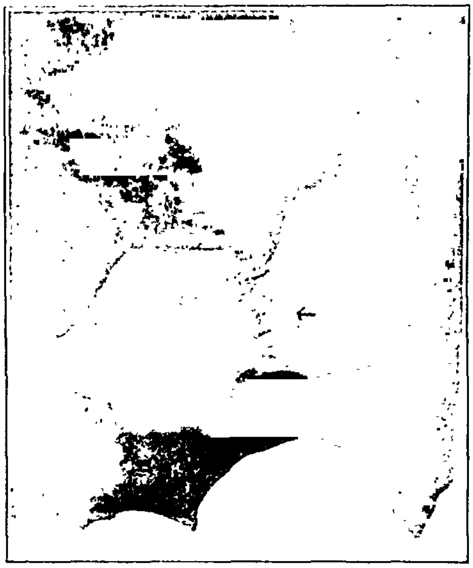

Fig. 4.—Gastric tumor in a person with achlorhydria. The patient suffered a gastric hemorrhage two months earlier but was otherwise symptomless. "Spot" film of stomach to demonstrate abnormalities observed fluoroscopically. Note rounded filling defect, which appears smooth and sharply defined, typical of a benign polyp. Above it is an elongated defect which was interpreted as a large fold. Because of a cardiac condition surgical treatment was not undertaken.

8. *Polypi.*—Polypi in the stomach have been shown to be precursors of carcinoma. Patients who have polypi should either be treated as if they had carcinoma or followed closely to determine malignant generation. As a practical approach to the problem it is ineffective, since polypi are usually discovered by routine examination and are associated with a relatively small percentage of gastric cancers.

MEANS FOR FACILITATING ROENTGEN EXAMINATIONS

The development of means by which the roentgen examination might be rendered less arduous, time consuming and expensive has also been studied to some degree. The possibilities here are as follows:

1. *Fluoroscopy Alone.*—Examination might be restricted to fluoroscopy only. This would, of course, produce a considerable saving in time and expense, although the saving may well be not as great as might be expected. The major expense involved in a good

roentgen examination of the stomach is the time of the roentgenologist, and this would not be decreased by simple fluoroscopic examination. It might rather be increased, since the fluoroscopist would be under compulsion to make an extremely thorough examination because of the absence of any roentgenographic checks. There are probably only a limited number of men in the United States whose fluoroscopic experience and ability are of such an order as to permit them to detect the small tumors which one would look for in such a mass survey. Our own experience has led us to believe that small lesions may well be overlooked even by experienced fluoroscopists and that the absence of any films for detailed study is a serious handicap. In the two series of cases which we have studied we have had some opportunity to test this procedure. At the beginning of the study both fluoroscopic and film examinations including "spot" films were used. As a result of the shortage of films, however, for a considerable period fluoroscopy alone was utilized. It is our impression that the results were not as accurate during this period.

The following 2 cases are cited to indicate the difficulties which may attend such a procedure. The first case was of a patient with pernicious anemia without gastric symptoms. She was examined carefully by a rather competent fluoroscopist and the stomach was thought to be normal. One of the roentgenograms made a day later is illustrated here (fig. 2). A rather small tumor measuring less than 1 cm. in diameter was clearly delineated on the lesser curvature and could be determined with considerable certainty. Reexamination with fluoroscopy after the discovery of this lesion led to some suggestive findings, although even on the second fluoroscopic examination the lesion was not clearly apparent. This is to be expected from the very nature of fluoroscopic study and illustrates well the possibilities of error in this procedure when done alone. Another case of similar character is illustrated in figure 3. This patient had achlorhydria, and the routine examination was done for this reason. There were no gastric symptoms. On fluoroscopy nothing was found. This fluoroscopist had not had much experience and the error might possibly be assigned to that. On the roentgenographic study the lesion was also overlooked, and I am certain that the major reason for this was the conviction of the roentgenologist that the stomach was normal because of the negative fluoroscopic examination. There is a small defect shown on the greater curvature, which proved to be an extremely small carcinoma of the posterior wall arising just on the pylorus. It was found during the course of abdominal exploration for a carcinoma of the cecum.

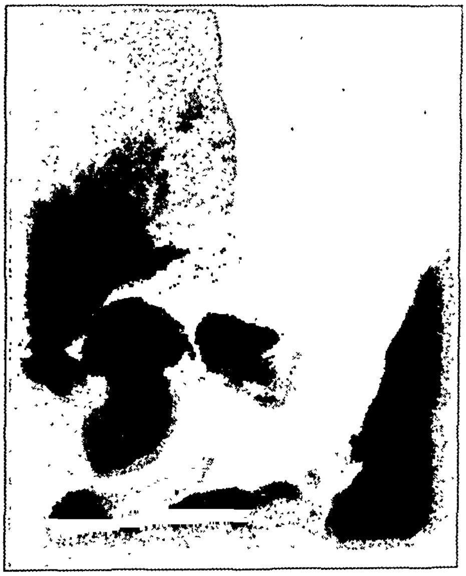

Fig. 5.—Same case nine months later. "Spot" film with some magnification as compared to figure 4. Three characteristic filling defects are seen. Pronounced increase in size has occurred, so much so that a diagnosis of carcinoma was made on the basis of the rapid growth. The stomach was resected and three movable, well encapsulated papillomas were found arising from a single stalk. The gross appearance was that of benign tumors but histologically there were found varying degrees of malignant change in different portions of the tumors.

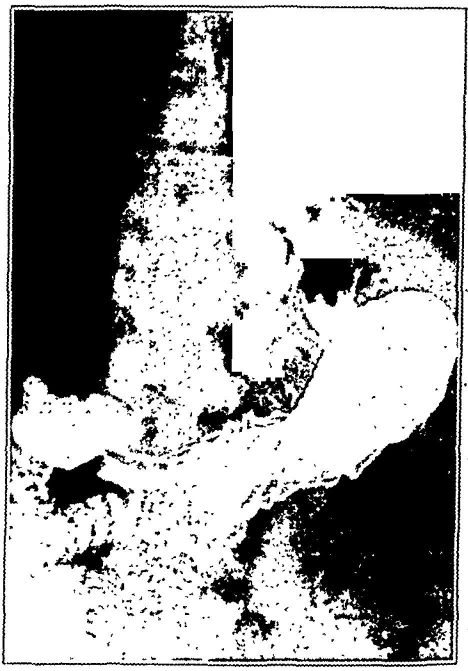

Fig. 6.—Carcinoma of the stomach in a patient with achlorhydria and no gastric symptoms. Posteroanterior roentgenogram on first examination, Oct. 23, 1946. A small rounded defect (arrow) in the middle third of the stomach was thought to be present but was difficult to demonstrate adequately either fluoroscopically or in the films. A tentative diagnosis of a tumor was made. The patient had syphilis of extensive character, so that surgical procedures were not undertaken until intensive therapy had been instituted, particularly since the diagnosis was in doubt and there was a bare possibility that the finding was due to a gumma.

2. *Roentgenographic Examination Alone Without Fluoroscopy.*—Roentgenographic examination alone is an expensive procedure if a sufficient number of films are to be exposed to make an adequate examination possible. For this reason it would probably not be the best method. It has the advantage of putting the entire burden of the technical examination on a technician. The films could be examined by the roentgenologist at his leisure. The large number of films involved and the elaborate technic necessary to make an adequate examination this way would result in considerable expense. It is doubtful that the results would be as accurate as desired.

3. *A Combination.*—A combination of fluoroscopy with "spot" films and a roentgenographic examination, as presently practiced by most roentgenologists, is, in some respects, the most expensive of all methods. It is without doubt the most effective method for the demonstration of small lesions, although even by this procedure some errors will occur. Such a combination

involves a good deal of work on the part of the roentgenologist and at the same time considerable technical work. In this combination the making of spot films by one method or another undoubtedly is of the first importance.

The possibilities of such a procedure are illustrated by the following case. A woman aged 70 years came in with a history of bleeding from the stomach several months before. There were no other gastric symptoms. On gastric analysis, achlorhydria was discovered. Fluoroscopic and roentgenographic examination was made. A small defect was detected in the middle portion of the stomach (fig. 4). By means of fluoroscopy and repeated films it was possible to demonstrate the mobility of the lesion and that there was no infiltration of the margins of the stomach. They were flexible and showed peristalisis extending throughout. It was thought to be a benign polyp. Gastroscopy was done and the lesion was observed. It was considered possibly malignant. The patient refused operation. Nine months later, simply as a matter of routine follow-up study, she was reexamined. There was no further blood in the stool nor any other symptoms. At this time the examination (fig. 5) revealed the presence of three fairly large defects clustered together which appeared to be somewhat movable. There appeared to be such a considerable increase in size of these lesions in the period of nine months which had elapsed that the probability of their having become malignant was seriously considered, despite the fact that there was no apparent infiltration, interference with peristalsis or fixation of the lesion. At operation a cluster of polypi arising from one stalk was found. Grossly they appeared to be benign. On microscopic examination, however, both benign and malignant tissue was found.

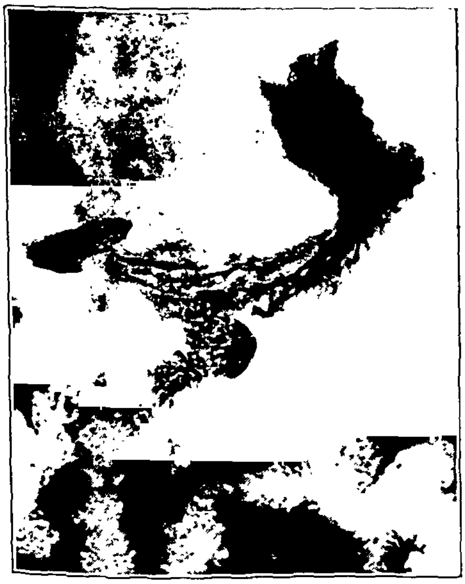

Fig. 7.—Same patient one month later. Careful study both on fluoroscopy and with roentgenograms failed to reveal any clear evidences of the defect previously seen. Note the good mucous membrane pattern in this roentgenogram made when the stomach was partially emptied. Further procedures were postponed pending the completion of the antisyphilitic therapy. There were still no gastric symptoms.

Another case is cited to illustrate the difficulties which occur even while using the combined examination, when extremely small lesions are under study. A patient without symptoms but exhibiting achlorhydria was examined in October 1946. An extremely small defect was observed but not clearly delineated (fig. 6). It seemed to be sharply demarcated. This patient had syphilis of an extensive character and it was thought wise to treat it before entering into any surgical program. Reexamination was done one month later, and critical examination of a number of roentgenograms made at that time revealed practically no evidence whatever of the process which had been previously observed (fig. 7). The fluoroscopist likewise was unable to make it out and some question arose as to the validity of the original diagnosis. Since the patient was still under strenuous antisyphilitic therapy and there were contraindications to immediate surgical treatment no immediate reexamination was made. Four months later, however, she was reexamined (fig. 8), and a characteristic rather large-sized defect was observed. At operation this was found to be a localized, somewhat polypoid type of carcinoma which was extremely well demarcated and measured about 3 cm. in its longest diameter. This case illustrates some of the difficulties which may be encountered in the detection of small lesions. It is not entirely possible to appreciate why this lesion was not discovered in the roentgenograms made two months after the original observation of an extremely small lesion.

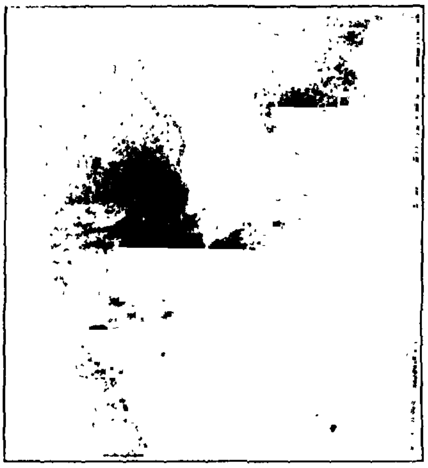

Fig. 8.—Reexamination four months later. "Spot" film reveals large, sharply defined, oval-shaped filling defect characteristic of a tumor. Obviously, rapid growth had occurred in the five months from the first study. The appearance was somewhat suggestive of an intramural tumor. There were still no gastric symptoms. Resection of the stomach revealed a well localized carcinoma measuring about 3.5 cm. in diameter. There was no extension beyond the stomach and no metastasis. The difficulties of the roentgen diagnosis of small lesions, the importance of frequent reexamination and the value of this type of study are all well illustrated by this case.

4. *Photofluorography.*—Photofluorography has been proposed as a means of rapid examination of large numbers of persons in whom routine examination is desirable. This has the great advantage of limiting the time needed by the roentgenologist to the smallest amount possible. The small size of film permits rapid interpretation. The rapidity with which the films can be exposed and their small size reduce the expense of the examination. A large number of views could be made, providing the technical factors were such as to permit this to be done without the risk of any undue radiation effects on the patient. Such a large number of films taken in a variety of positions and with varying amounts of barium in the stomach might constitute a

fairly adequate examination, and considerable accuracy might be achieved. The device would be time saving to the roentgenologist and relatively inexpensive.

In this connection attention should be directed to the method of de Castro.[7] He uses a photofluorographic unit which is so designed as to permit manipulation of the patient into almost every position and rapid exposure of the films almost in motion picture fashion. The apparatus has the great advantage of having a slit through which examination can be made to determine the position of the barium and of the patient's stomach at the time when exposure is to be made. Adequate localization can thus be achieved without difficulty and the results are accordingly better than in cases in which focusing is done rather blindly.

It is obvious from the foregoing discussion that none of the short cuts are entirely satisfactory, and in none has there been any adequate proof of accuracy except for a few small series which have been previously attempted. It seems reasonable to propose that a number of studies should be undertaken on a small scale in various portions of the country by these various methods in order to ascertain how accurate each is and how rapidly and inexpensively they could be achieved.

A number of efforts have already been undertaken in the field of the routine examination of symptomless persons by a variety of methods. Beginning in 1939 some of my associates and I have examined patients with pernicious anemia at semiannual intervals. The results of this have been previously reported.[1] At the present time 248 cases have been studied and carcinomas have been found in 6 per cent, and benign polypi in approximately 7 per cent. In this series, as previously reported, many small benign lesions have been discovered and, in addition, a number of small carcinomas.

A study of symptomless but otherwise unselected persons over the age of 50 has been carried out by St. John, Harvey and Swenson.[8] These investigators used the fluoroscopic method alone, reexamining with roentgenograms when there was some specific indication. They found two carcinomas, one lymphosarcoma and no polypi. The small number of tumors which they discovered was somewhat disappointing but indicates how unproductive such a procedure may be if there is no selection of patients except on a basis of age. The possibility that one or two more lesions might have been discovered if a more elaborate form of examination had been used should be considered, since the incidence is reputed to be somewhat higher than the number which they found.

In another series, Dailey and Miller[9] examined 500 patients and found no malignant tumors in this small series. There was one polypus seen.

During the past two years, in cooperation with the Department of Surgery and the Out-Patient Department of the University of Minnesota, we have had opportunity of studying another series of patients. Roentgen examination of the stomach has been done on these patients at semiannual intervals. The patients have been selected with three criteria in mind. They were all over the age of 50, had no particular gastric symptoms and showed either achlorhydria or free hydrochloric acid of less than 30 units in the gastric contents. In most of the cases the gastric analysis was done after the triple histamine test. In some cases two doses of histamine were used; in a few cases only one dose. Approximately 30 per cent of all persons on whom gastric analysis was performed fell into the group.

To date 544 such persons have been examined. We have found, by roentgen examination, 3 cases of gastric carcinoma which have been proved. One additional case, reported in a foregoing paragraph (fig. 3), should have been found but was missed as a result of an error in interpretation. The lesion was discovered during the course of an operation for another tumor. There were, in addition, some 11 other cases of gastric carcinoma in this series, but these are not considered since they were not entirely symptomless. In a few cases the symptoms were either remote or minor as illustrated by 1 of the cases cited (figs. 4 and 5), but they do not fall within the category of truly symptomless persons.

In the same series there were found 19 patients with gastric polypi, presumably benign. Most of these have been confirmed either by gastroscopy or at operation. Small as they are, it is possible that there are some actual malignant growths among them. Only time will determine this definitely. The finding of these small tumors is of great importance, since this group is no doubt the most susceptible of all to the development of carcinoma and will be observed frequently for evidences of rapid growth or other signs of malignant change as in the cases reported (figs. 4, 5, 6, 7 and 8).

The greater productivity of the roentgen examination in such a selected group as compared with those reported by others is well brought out by the large number of tumors discovered. Although the incidence is far less than that found in pernicious anemia it is of a sufficiently substantial order to justify the effort made. We are convinced that one of the reasons for the discovery of so many small tumors, particularly the large number of polypi, is the thoroughness of the roentgen study, which included, in most cases, prolonged, painstaking fluoroscopy, "spot" films and roentgenograms in several positions.

In addition to the tumors numerous other abnormalities in the stomach and duodenum were observed. As might be expected in such an age group there were an appreciable number of hiatus hernias, apparently symptomless. A few cases of duodenal deformity were discovered. There were a number of cases of enlarged gastric rugae which gave great difficulty in differentiation from polypi. It should be noted that gastroscopy was used frequently for confirmation or further elucidation in the positive or doubtful cases.

Further studies are being carried out with other criteria for the selection of the patients to have roentgen examination. The details of these studies as well as other details of the study are being reported by State.[5b] It is our impression that the results of our studies indicate the feasibility and the value of the routine roentgen examination of symptomless persons for the discovery of gastric tumors.

SUMMARY

Routine roentgen examination of symptomless persons is the only presently effective means for the discovery of gastric tumors in an early stage of their development.

While the error inherent in the examination will be greater in such cases than in patients with symptoms, the procedure is capable of discovering most of the tumors present, even if of extremely small size.

The incidence of gastric tumors is small and the expense per examination is large.

Methods for the selection of persons for roentgen examination and methods for reducing the expense of the procedure are discussed.

In 544 symptomless persons over the age of 50 whose gastric contents showed either achlorhydria or free hydrochloric acid of less than 30 units, three carcinomas and nineteen presumably benign polypi were discovered by routine roentgen examination.

ABSTRACT OF DISCUSSION

Dr. Paul Swenson, Philadelphia: I am particularly pleased to discuss Dr. Rigler's paper because he refers to the attempt my colleagues and I made some years ago at a mass survey. Also, I am happy to know that a good friend and colleague has the same philosophic approach to the problem. If the members of the medical profession are going to do anything about the cancer problem before the biochemist has solved it, the only hope for enhancement of their work is to arrive at a better means of early diagnosis, which, as Dr. Rigler said, is still a problem in spite of the fact that the surgeon has better technics and that postoperative care is so good. Patients still report in relatively far advanced stages and something has to be done in order to pick out the early cases. Such a survey as this may be just as important as the mass surveys of the chest being done these days, if not more important. The best and most important results in mass surveys of the chest are found in special groups such as food handlers, hospital attachés and so forth, where there is a particular hazard in having a lesion of the chest present, and in that respect these special groups that Dr. Rigler has worked on certainly offer a good plan of procedure. It is discouraging to find but 3 cases of a malignant nature among 2,500 persons, as we did. Nevertheless, one must not forget that it was important to those three persons. We are continuing with this problem at Jefferson by adapting our photofluorograph to this method. It will have a few advantages. The patient can come in at any time. He does not have to report at a specified time when the fluoroscopist can be present, and more than one person can view the films. As we were doing it back in 1939 it was purely a one man show, and if the fluoroscopist was not alert the case was missed. There will be cases of that kind from time to time and there will be an advantage in having films in oblique and anterior-posterior projections which can be viewed by more than one person for discussion. There is also the safety factor to consider, less exposure being necessary to this fluoroscopist. We have found the danger to the patient is not too great in a single examination. Dr. Rigler has some early cases to show you in his roentgenograms, but I do believe that you can find early lesions with the fluoroscope as well. The fluoroscope can also pick them up early. I hope it does not sound too arrogant on my part to say that in our routine work some of our films have failed to show some things which we saw in the fluoroscope. Later, we went back to the fluoroscope because we doubted the films, and proved the lesions by both methods the second time. One can become that adept at picking up early lesions if one is careful and does not have to give oneself or the patient too much exposure to do it.

Dr. Leo G. Rigler, Minneapolis: I want to underline what Dr. Swenson said about surgical therapy. One surgeon reported on 60 cases with a 4 per cent mortality, and when surgeons can do that one gets some idea of how the surgeons have progressed in their part of the program. I do not wish to advocate at this time general mass surveys over the United States, as a number of persons have suggested. I do think what is needed is a number of pilot experiments going on in several institutions. We are carrying on some in selected groups with the fluoroscope, spot films and roentgenography. Dr. Swenson has told you of his work with photofluorography. I think that is extremely important and that there should be other experiments to determine the best answer to this problem.

STUDIES ON HYALURONIDASE

DELBERT M. BERGENSTAL M.D.*
and
WILLIAM WALLACE SCOTT, M.D.
Baltimore

The enzyme hyaluronidase has been implicated in the process of fertility primarily as the result of the following reports.

McClean and Rowlands [1] and Fekete and Duran-Reynals [2] showed that the ovum in the fallopian tubes is covered with many follicular cells which are embedded in a thick, viscous gell-like material. Before the sperm can penetrate the ovum, these cells must be dispersed and the sticky gel covering removed. This material which holds the follicular cells to the ovum has been shown to be hyaluronic acid, a polysaccharide, which, according to Meyer and Palmer,[3] is composed of equal molecular parts of glucuronic acid and acetylglucosamine. This polysaccharide forms a loose combination with body proteins and appears to play an important role as an intercellular cement. It is found in all mesenchymal tissue and is in high concentration, especially in human umbilical cord, synovial fluid and pleural and ascitic fluid of patients with mesotheliomas. Hyaluronic acid is soluble in water and forms an extremely viscous solution.

Hoffman and Duran-Reynals [4] and McClean [5] in 1930 observed that extracts of mammalian testis contained factors which profoundly modified the permeability of connective tissue and that this alteration in permeability was due to the action of the extract on hyaluronic acid. These factors became known as "spreading factors" because of their action in causing ink or dye, injected intradermally, to spread over wide areas. In 1934, Meyer and Palmer [6] gave the name hyaluronidase to an enzyme which they found in autolysates of a rough type II Pneumococcus and which was capable of hydrolyzing hyaluronic acid. Subsequently, Chain and Duthie [7] showed that the hyaluronidase activity of testicular extracts was similar to the activity of the testicular "spreading factor" of earlier workers.

McClean and Rowlands [1] found that testicular hyaluronidase added to recently ovulated ova caused a dispersion of the follicular cells, denuding the ova, but without apparent damage. They were the first to suggest that a type of sterility exists in which there is an insufficient concentration of hyaluronidase in sperm to disperse the follicular cells. Fekete and Duran-Reynals [2] and Leonard and Kurzrok [8] confirmed this dispersing effect on the mouse and rat ova respectively.

In 1944, Rowlands[9] showed that artificial insemination of rabbits with semen containing a sperm concentration known to be inadequate for fertility resulted in no pregnancies. If a sperm-free hyaluronidase filtrate was added to this inadequate semen sample, four out of five experiments resulted in fertilization of the ovum.

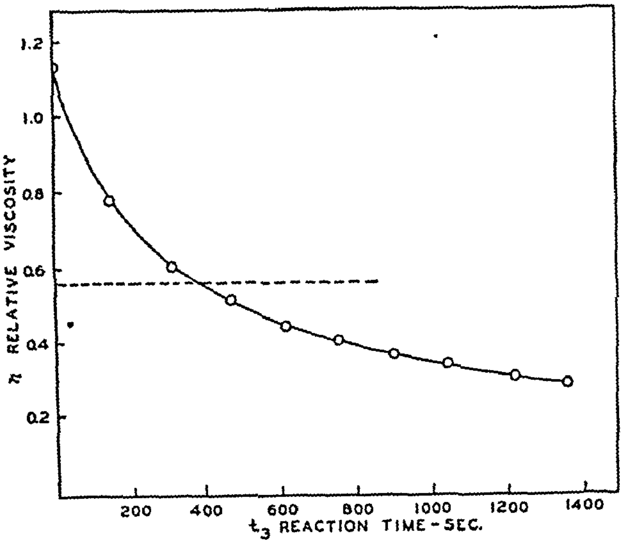

Chart 1.—The decrease of viscosity as a function of hyaluronidase concentration and time.

In the past two years renewed interest has been shown in this enzyme system as regards its role in fertility. Joel and Eichenberger,[10] Greenberg and Gargill[11] and Werthessen and colleagues,[12] by use of viscosimeter technic, studied the activity of human semen. Werthessen showed that the sperm count was roughly proportional to the hyaluronidase level.

Kurzrok and associates[13] have recently studied the semen of 90 patients with sperm counts ranging from 0 to 400,000,000 per cubic centimeter. Hyaluronidase activity was measured by a turbidity ring test. They concluded that hyaluronidase increased directly with sperm count up to 100,000,000 sperm per cubic centimeter. Beyond this the hyaluronidase did not increase proportionally to the sperm count. Furthermore, several specimens of semen with high counts did not contain hyaluronidase. These latter specimens were considered infertile. Mixing of semen and bull testis hyaluronidase or cervical packing with hyaluronidase before normal coitus was reported to have increased the number of successful fertilizations.

The purpose of the research to be presented here was to obtain more information about the relationship of sperm count to hyaluronidase concentration, the rate and site of formation of this enzyme and the enzyme content of structures of the genital tract and their secretions.

METHODS

Substrate.—Hyaluronic acid was isolated from human umbilical cord as described by Haas.[14] A solution containing 6 to 8 mg. of the dry powder per cubic centimeter of 0.02 molar acetate buffer of p_H 4.7 was made and stored at low temperature. Slight variations in substrate concentration had no effect on the accuracy of determining the concentration of hyaluronidase of a standard preparation in repeated determinations.

Enzyme.—Hyaluronidase used in calibrating the viscosimeters employed in the determination of unknown concentrations of this enzyme was prepared from bull testis by the method of Madinaveitia and Quibell.[15] An active stable preparation was obtained by extracting fresh bull testis with 0.1 normal acetic acid, fractionation with ammonium sulfate between 0.3 and 0.7 saturation, dialysis of the neutralized solution, and drying by lyophilizing.

Viscosimetric Assay of Hyaluronidase.—The viscosimetric technic, as described by Chain and Duthie[7] and Madinaveitia and Quibell[15] and later modified by Haas,[14] was used. This enables one to measure quantitatively the decrease in viscosity due to depolymerization of hyaluronic acid. The decrease of viscosity as a function of hyaluronidase concentration and time is shown in chart 1. The time required to diminish the viscosity of the substrate to 50 per cent of the original level is called the half life time, R_0. Since the reaction is believed to be unimolecular, the rate equation $K = 1/t \log a/a - b$ will hold (a = initial concentration of hyaluronic acid; b = concentration of hyaluronic acid at half life time; t = half life time in seconds, or R_0). Log $a/a - b$ will remain constant and may be dropped, giving the equation $K = 1/R_0$. To make K an easier value with which to work $1/R_0$ has been multiplied by 10^4. Thus $K = 1/R_0 \times 10^4$ (1/sec.) is an expression of the hyaluronidase activity. Values for K are directly proportional to hyaluronidase concentration.

Collection, Preparation and Examination of Specimens of Semen.—All specimens of semen were collected in clean glass containers and obtained by masturbation either in the clinic or at home. Time of collection was noted in each instance, and samples were stored in the ice box if not used immediately for determination. Time from collection to enzyme determination varied from twenty minutes to four hours. Time relations will be discussed. All specimens were examined for volume, number of spermatozoa, leukocytes, percentage of abnormal forms, motility and hyaluronidase activity.

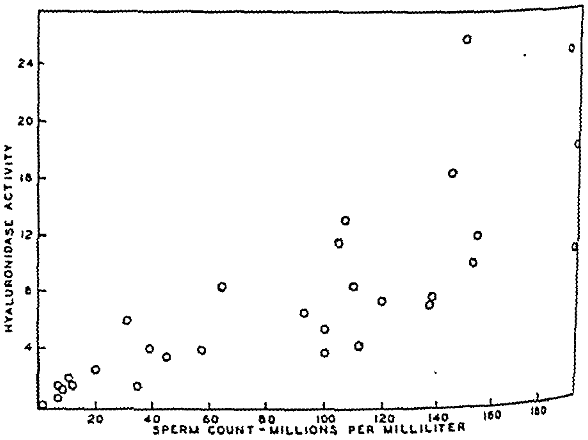

Chart 2.—The relation of sperm count to hyaluronidase content of semen.

In order to learn more of the rate and site of formation of hyaluronidase, partition and treatment of whole semen was carried out as follows:

Seminal Plasma and Whole Sperm: Centrifugation of the ejaculate as received at 3,000 revolutions per minute for ten minutes resulted in separation into a supernatant phase (seminal plasma) and a sediment (whole sperm).

Homogenized Whole Semen: In all experiments in which homogenized semen was used it was prepared in the following manner. After centrifugation of 0.5 cc. of semen and removal of the seminal plasma, to the whole sperm was added 0.5 cc. of 0.2 molar borate buffer, *p*H 6.7, and 0.7 cc. distilled water. This sample was then homogenized in a glass homogenizer for three to five minutes. The homogenate was added back to the seminal plasma previously removed by centrifugation. This we refer to as homogenized whole semen. Direct homogenization of the semen produces excessive foaming which leads to errors in measurement and transfer.

Homogenized Sperm and Whole Sperm: Wherever it was desired to study the amount of enzyme remaining in the sperm, a procedure similar to that described for homogenized whole semen was used. However, the supernatant fluid was heat inactivated before combination with the homogenized sperm This we refer to as homogenized sperm. Whole sperm obtained by centrifugation after combination with heat inactivated seminal plasma is referred to as whole sperm.

Other Genital Fluids and Tissue: Prostatic and seminal vesicle fluids of man were obtained by collecting ejaculate from two patients after vasectomy. Prostatic fluid of the dog was obtained from animals having prostatic fistulas prepared according to the method of Huggins and associates.[16]

Prostatic and testicular tissue of man after homogenization in phosphate buffer were tested for hyaluronidase activity.

Spermatocele fluid, obtained in two instances by aspiration from human beings, was tested for hyaluronidase activity.

RESULTS

Relation of Sperm Count to Enzyme Activity.—Table 1 shows the analyses of 34 cases. The relation of sperm count to enzyme activity is shown in chart 2. In this series hyaluronidase activity is roughly proportional to sperm count. The fact that this relation is not directly proportional is of some interest in the problem of sterility and will be discussed later. It is important to note that in every case in which sperm were present in a specimen that specimen contained hyaluronidase activity; in all cases in which sperm was not present, no hyaluronidase activity was found.

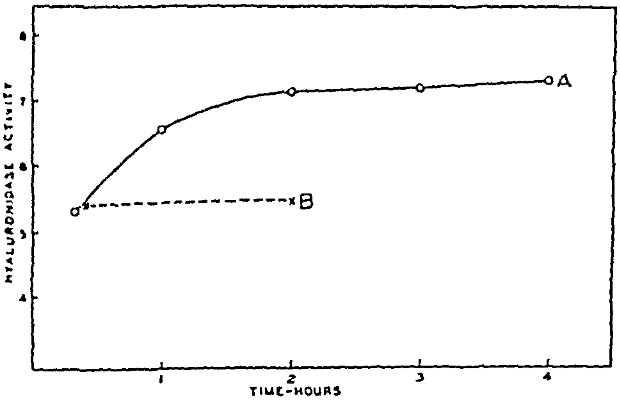

Chart 3. The change in hyaluronidase activity with time. *A*, whole semen (solid line). *B*, homogenized whole semen (interrupted line).

There seems to be no clearcut relation of hyaluronidase activity to volume of ejaculate, motility of spermatozoa, the number of abnormal sperm or the number of leukocytes present in the semen.

The patients showing aspermia consisted of 1 who had suffered an irridiation accident, 1 eunuch, 1 on whom vasectomy had been done and 2 persons in whom the cause was not apparent after examination.

Site and Rate of Formation of Hyaluronidase.—As the analysis of samples of semen progressed it became clear that a direct relation did *not* exist between sperm count and hyaluronidase activity. Several questions arose including the site of formation of hyaluronidase and the rate of release or formation of the enzyme.

Table 2 shows the differential analysis made on several semen samples. These samples were analyzed within four to six hours after collection. All samples of seminal plasma contained approximately as much enzyme as did whole semen. This would indicate that during the determination diffusion or release of hyaluronidase did not occur. For example, in case 22 (table 2) there remained a rather large amount of enzyme in the sperm which was liberated on homogenization.

Characteristics of the Normal Secretion; the Influence of Thyroid, Suprarenal, and Testis Extirpation and Androgen Substitution on the Prostatic Outout, J. Exper. Med. 70: 543-556. 1939.

The amount of hyaluronidase remaining in sperm is not constant for the various samples. This may represent a variable rate of release of the enzyme by the sperm. In case 24 (table 2) the analyses of homogenized sperm and whole sperm indicate that both contained additional enzyme. Whether in the case of whole sperm this represents absorption, diffusion or manufacture is a matter of conjecture.

Studies to determine the rate of release, or formation of enzyme are illustrated in figures 3 and 4.

Figure 3 *A* illustrates the rate of increase of hyaluronidase in whole semen with increasing time. This sample contained 100,000,000 sperm per cubic centimeter. At the times indicated aliquots of whole semen were analyzed for enzyme. Increasing hyaluronidase activity was observed for the first two hours, leveled off and remained rather constant for the third and fourth hours. This could indicate production and release, or release only.

In figure 3 *B* is shown the result of work to determine whether there is continued formation of enzyme within the sperm over a period of hours or whether most of the hyaluronidase is present or formed before ejaculation (or within a few minutes after ejaculation) and is gradually released from the sperm. This sample contained 70,000,000 sperm per cubic centimeter. Twenty minutes after collection of this ejaculate an aliquot was homogenized as described for the preparation of homogenized whole semen. This should indicate the total hyaluronidase present in both seminal plasma and sperm at that time. The remaining whole semen was permitted to stand at room temperature for two hours and a second aliquot homogenized. The hyaluronidase activity of the two hour sample was only slightly greater than that of the 20 minute sample, and indicated that in this ejaculate there was little enzyme formed twenty minutes after ejaculation. This has been confirmed to a similar degree in other experiments.

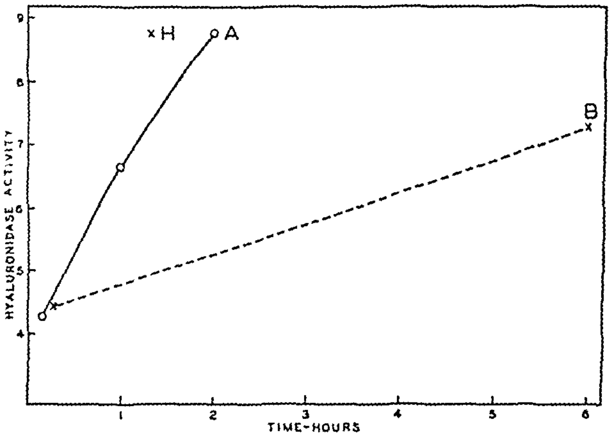

Chart 4.—The release of hyaluronidase activity with time.

Figure 4 *A* shows again that the sperm may contain large amounts of hyaluronidase and gradually release it into the seminal plasma. In this instance at the end of two hours enzyme activity had increased from 4.3 at ten minutes to 8.8. (The sample contained 100,000,000 sperm per cubic centimeter.)

Figure 4 *B* shows an increase from 4.4 to 7.3 in six hours. (The sample contained 150,000,000 sperm per cubic centimeter.) An aliquot of this specimen was homogenized at eighty minutes (homogenized whole semen) and its enzyme activity determined to be 8.7 (point H on graph), a value higher than for the amount of enzyme released in six hours. This would indicate a capacity of the sperm in this ejaculate to liberate more enzyme in time.

Spermatocele Fluid.—Consideration was next given to the question whether sperm can release or form hyaluronidase without contact with prostatic and seminal vesicle fluids. Fluid from two different spermatoceles was examined for enzyme activity. In both extremely high concentrations were found; both contained many spermatozoa, predominantly nonmotile. A comparison of "supernatant spermatocele fluid" and "homogenized whole spermatocele fluid" revealed little difference in enzyme content.

Prostatic and Seminal Vesicle Fluid.—In 2 patients with vasectomy no hyaluronidase was found in the ejaculate. Five dogs previously prepared with prostatic fistulas and orchidectomized showed no hyaluronidase activity in the prostatic fluid.

Human Prostatic and Testicular Tissue.—Homogenates of 3 human prostate glands removed for benign hyperplasia contained no hyaluronidase. Testes from 2 patients over 50 years of age castrated for prostatic cancer showed small amounts of the enzyme. Histologic sections of these testes revealed moderate tubular atrophy and decreased spermatogenesis.

COMMENT

Although there appears to be no direct proportionality between sperm count and hyaluronidase activity, the two appear to be related. In our experience all ejaculates with sperm showed enzyme activity. Our findings indicate that hyaluronidase is either derived from the sperm or closely associated with them. The mechanism of "carry" has not been determined.

The site of formation of hyaluronidase has not been determined, but the absence of the enzyme in the vasectomized human being demonstrates that the enzyme is derived from the genital tract above the vas deferens. Furthermore, whereas human testis homogenates contain the enzyme, prostate does not. It should be recalled that the commercial source of hyaluronidase is the bull testis, which is extremely high in the activity scale.

The rate of formation of hyaluronidase in the human being appears difficult to determine. Our studies in which the enzyme concentration of homogenized whole semen was determined at intervals after ejaculation indicate that within a short time after delivery to the outside maximum concentrations are observed. There appears to be no further production of the enzyme with time. Increase in enzyme concentration in whole semen with time may be a function of diffusion. This rate of release may be influenced by many factors, including those added by admixture with seminal vesical and prostatic fluid. Apparently these fluids do not influence production.

SUMMARY

A viscosimetric method for the determination of the enzyme hyaluronidase in human semen is discussed.

Hyaluronidase activity of 34 specimens of human semen has been determined. The level of this enzyme is only roughly proportional to the sperm count. In all instances absence of sperm was associated with absence

of enzyme. All specimens with sperm contained hyaluronidase.

Hyaluronidase appears to be derived from the sperm or closely associated with them. At or shortly after ejaculation concentration of hyaluronidase in homogenized whole semen appears to be maximal. There is a gradual increase in the enzyme content of whole semen with time. This appears to represent diffusion from sperm to seminal plasma and not continued production.

The hyaluronidase content of certain genital tissues and fluids is presented.

ABSTRACT OF DISCUSSION

Dr. A. E. Goldstein, Baltimore: Dr. Scott made mention that the hyaluronidase is in the sperm itself and the fluid. Has he determined the normal amount of hyaluronidase carried in one ejaculate? If the sperm contains the hyaluronidase and a normal amount of hyaluronidase is present, does each sperm carry some hyaluronidase or can a person have a normal amount of hyaluronidase and sometime some sperm not have any hyaluronidase, so that when it meets with the ovum that hyaluronic acid will not cause a dissolution of the mucoid substance? My colleagues and I have been interested in hyaluronidase in the laboratory, and in using the extracts of hyaluronidase. I am anxious to know how the hyaluronidase reaches the ovum, whether it goes through with the sperm or with the seminal fluid. I am sorry that I have to disagree with Kurzrock's article, with his thoughts about the hyaluronidase in fertility. Seigler carried out a series of experiments similar to the experiments that Kurzrock carried out and got the opposite results.

Dr. Henry Sangree, Philadelphia: This is an important paper, and I believe it is epoch making in the treatment of infertility. Dr. Scott's investigations with hyaluronidase parallel in importance the research work of Dr. Huggins, of Chicago, on prostatic enzymes and subsequent treatment of prostatic cancer. I am interested in the relation of hyaluronidase to endocrine studies, particularly in its relation to thyroid and pituitary endocrine secretion. Can Dr. Scott give us any further information on Ringer's solution, used, I believe, considerably by gynecologists and obstetricians for its spermatokinetic action. In an exhibit at this meeting of the American Medical Association of 222 cases involving male fertility, the doctors are much more interested in the modern endocrine knowledge of fertility than in operative or other forms of clinical treatment. My endocrine treatment to date has been extremely unsatisfactory. I want to congratulate Dr. Scott and his colleagues for their epoch making discoveries and investigations in this important field of study.

Dr. W. W. Scott, Baltimore: With regard to the amount of hyaluronidase in a single ejaculate, we are not sure just how much there is on a weight basis. Furthermore, we do not know whether the individual sperm carries hyaluronidase. At present, our methods are not capable of sorting out one sperm and detecting the enzyme content in that particular sperm. As to how the enzyme reaches the ovum, we do not know. We do not know whether the hyaluronidase reaches the ovum by the sperm or in the fluid. This requires further work. As to endocrine relations to enzyme concentration, we are reasonably sure that there is a relationship between production of androgen by the testis and the production of the enzyme. We are reasonably sure that there is a relationship to the pituitary and the testes. An animal that has had a hypophysectomy shows a diminution in the amount of hyaluronidase in the ejaculate. The same holds after removal of the testes. Furthermore, there is a definite relationship to protein deficiency. Rats placed on protein deficiency diets show azoospermia, which is reversible when protein feeding is resumed. They also show a decrease in the amount of enzyme present in the testis with a restoration to normal if protein feeding is carried out.

URETHROCYSTOGRAPHY IN THE MALE CHILD

M. LEOPOLD BRODNY, M.D.
and
SAMUEL A. ROBINS, M.D.
Boston

Urethrocystography is a well established diagnostic procedure in the adult,[1] but its merits in infants and children are insufficiently recognized. The paucity of the literature on the subject is sufficient proof of this. In over three hundred papers and monographs and in highly specialized roentgenographic and urologic texts[2] references to urethrocystographic studies in children are meager or inadequately presented.

Urethrocystoscopy in children is considered a formidable procedure. The necessity of hospitalization and anesthesia often results in procrastination by parents, and technical difficulties cause temporization by the physician. There is therefore need for a simple, painless and safe substitute for the endoscopic examination. We believe that urethrocystography is valuable for investigation of organic uropathy in pediatric patients. The simplicity of urethrography in children is advantageous. It is an office or dispensary procedure; anesthesia is not necessary; the ordinary x-ray apparatus, one or two simple instruments and a proper opaque medium are all that is required. This method presents a permanent graphic record for systematic study of the existing conditions, for the evaluation of prospective treatment and for the appraisal of results. It minimizes the danger of infection and trauma to the tissues. In many conditions in which cystoscopy is impossible or impractical urethrography is the only method of choice.

This paper is based on roentgenographic investigations carried out in over 250 male patients under 16 years of age. The study is not scientifically exhaustive, but is presented to demonstrate the clinical importance of this procedure in the pediatric patient. Additional experience, and correlation of the roentgenographic observations with the anatomic changes produced by the lesions of the urethra and its appendages, will make urethrocystography as valuable for the study of the lower urinary tract as pyelography is for the diagnosis of renal disease.

INDICATIONS

Urethrocystographic examination is indicated in every male child with suspected obstructive uropathy, persistent or recurrent pyuria, nocturnal and diurnal enuresis[3] and other symptoms related to the lower part of the urinary tract. It is also important for the evaluation of postoperative results and in the study of the physiology of micturation and its variations from the normal.

There are two methods of urethrocystographic study: the retrograde and voiding. Both may be necessary for a complete study. Voiding urethrograms depict the urethra in the physiologic state of micturition; retrograde urethrograms visualize it in a state of distention. In the former, the sphincters are opened by the nerve mechanism of the patient and the pressure is exerted from the bladder distally; in the latter, the sphincters

are opened by the force of the injected mediums and the pressure is exerted from the meatus proximally to the bladder.

CONTRAINDICATIONS

The contraindications are urethral bleeding, acute local infections and recent instrumentation. This procedure should be painless. Improper technic, especially too great pressure on injection, may cause extravasation or reflux into the venous system. Age is not a contraindication to urethrography; it has been satisfactorily employed in infants. The voiding method is impractical in patients who are unable to urinate on command.

TECHNIC

The patient is routinely prepared as for any abdominal roentgen examination. He is then instructed to empty his bladder. A flat roentgenogram of the abdomen is taken so as to include the kidneys, ureter and bladder. This picture will reveal the presence of calculi, abdominal masses and spina bifida occulta. If the kidneys are not well outlined or appear abnormal in size, shape or position, urographic studies are indicated.

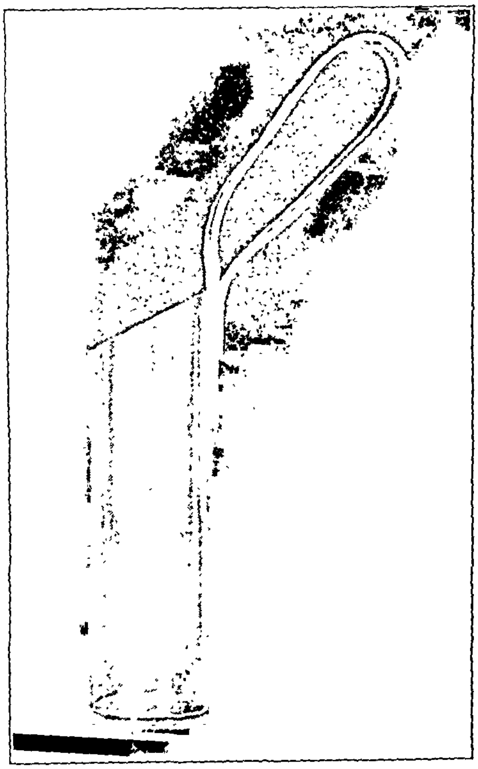

Fig. 1.—A Nonopaque transparent plastic receptacle to facilitate voiding urethrography. The urinary stream is under continual vision and the *urine can be collected without the patient's wetting himself.*

OPAQUE MEDIUMS

Various opaque mediums such as iodized oil, chloriodized oil, sodium iodide, methiodal sodium and acacia have been used. We now employ a new substance, "rayopake,"[4] which is superior to the iodized oils for urethrocystography. "Rayopake" contains 4.8 per cent of a "viscosity base" (a polymeric form of polyvinyl alcohol) and 50 per cent of the diethanolamine salt of 2,4-dioxo-3-iodo-6-methyl-tetrahydropyridine-N-acetic acid. This medium mixes with water and urine, flows easily, is well tolerated by the mucous membrane and produces a homogeneous shadow with sharply defined outlines. The opacity of "rayopake" can be controlled by dilution with water; we use a dilution of 20 per cent for cystography and one of 50 per cent for urethrography. The medium does not break up into globules when mixed with the urine in the bladder. Instruments and catheters are easily cleansed with warm water after their use. "Rayopake" does not deteriorate rubber or support bacterial growth. It is especially valuable for voiding urethrograms, and can be easily voided in a steady stream which has sufficient density for satisfactory roentgenograms. A complete report on "rayopake" in urethrocystography is now in press.[5]

CYSTOGRAPHY

A small rubber catheter is passed into the bladder under aseptic precautions and the amount of residual urine is determined. A culture and sediment of the catheter specimen are obtained. The bladder is then filled with the sterile opaque medium (20 per cent solution of "rayopake") until the patient complains of a desire to void. The quantity of the solution is noted. This amount varies with age. A simple guide to the normal limits is 50 to 100 cc. at age 5, 100 to 150 cc. at age 10, 150 to 200 cc. at age 15 and the normal adult capacity at age 20. The sensitiveness of the bladder and the muscle tone can be gaged by this maneuver. The central rays are directed over the pubis. A rapid exposure is desirable. Anteroposterior and oblique views are used.

URETHROGRAPHY

Voiding Urethrogram.—There are two methods of obtaining satisfactory voiding urethrograms. postcystographic and posturographic. These will now be described.

Postcystographic Method: The bladder is filled with 50 per cent "rayopake" until the patient has a desire to void. He is then placed in a position halfway between the dorsal and lateral so that the pelvis forms an angle of 45 degrees to the film. The leg nearer the Bucky diaphragm is flexed and abducted, and the other leg is fully extended. The central rays are directed about 1 inch (2.54 cm.) medially to the middle of Poupart's ligament, and 8 by 10 cm. or 10 by 12 cm. films with screens are used. The patient is given a nonopaque plastic container specially designed for voiding (fig. 1) and is instructed to do so. When the stream has assumed its full force, a rapid exposure of the bladder and urethral region is made. The patient is instructed to cease voiding and is rotated back to the dorsal position. The target of the roentgen ray tube is centered over the root of the penis and the voiding and exposure technic is repeated. Another roentgenogram is taken of the bladder after voiding to determine whether any of the opaque medium has been retained.

Posturographic Method: In children, satisfactory urethrograms can be obtained by utilizing the concentrated medium (iodopyracet compound solution[6]) that collects in the bladder after excretory urography. After completion of the roentgenographic study of the upper part of the urinary tract, a voiding urethrogram is obtained in the manner which has been described. This procedure enhances the diagnostic value of intravenous urography by furnishing information about the lower as well as the upper part of the urinary tract. We believe that urethrographic study by the posturographic method should be a routine of excretory urography in children.

[6] "Diodrast," manufactured by Winthrop Chemical Company.

Retrograde Method.—A penile clamp with a syringe for urethrography has been previously reported by one of us.[7] It is comfortable to the patient, and the hands of the operator can be protected from exposure to the roentgen rays; it facilitates the injection and permits awaiting development of the film in the different positions. A special metal tip to fit the end of the cannula has been devised for use in infants and children.[8] It tapers to a point small enough to obturate the urethral meatus. If the glans is too small for clamping, a gauze strip wound around the penis behind the corona will permit a firm grip. The syringe is filled with 10 to 15 cc. of "rayopake" and is attached to the cannula of the clamp. In order to outline the prostatic urethra, the exposure must be made while the injection is in progress. Complete exploration of the entire urethra requires two views, anteroposterior and oblique; sometimes a lateral projection is also necessary. Stereoscopic films are of value in some cases. Patience and gentleness will facilitate examination and instil confidence in the youthful patient. The technic is the same as for voiding urethrograms.

ANATOMY OF THE MALE URETHRA

The male urethra begins at the internal sphincter of the bladder, perforates the prostate in a slightly concave curve from the base to the apex, passes through the triangular ligament and continues along the ventral surface of the penis to the tip of the glans. The urethra is arbitrarily divided by the triangular ligament into an anterior or cavernous portion and a posterior or muscular portion.

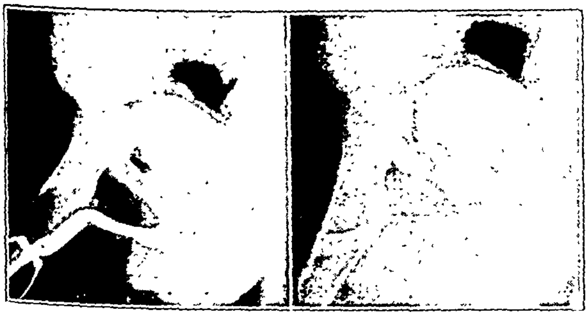

Fig. 2.—E.G., aged 7. Left, retrograde. Right, voiding. Note the widening of the supracollicular portion of the urethra and the semilunar cusplike defect caused by the valves. The bladder is trabeculated with numerous small sacculae. The verumontanum is not visualized on the voiding urethogram. The urethral canal below the obstruction appears narrowed because of the deficiency of the stream.

The length of the urethra varies with age. It is 6 cm. at birth, 7 cm. at 5 years of age and 8 to 9 cm. at 16 years. The adult length varies from 14 to 22 cm. and is attained at 18 to 20 years of age.

There are three normal areas of narrowing of the urethral canal: the internal sphincter, the external sphincter and the urethral meatus. There are also three normal areas of dilatation: the fossa navicularis, the bulbous part of the anterior urethra and the collicular portion of the prostatic urethra.

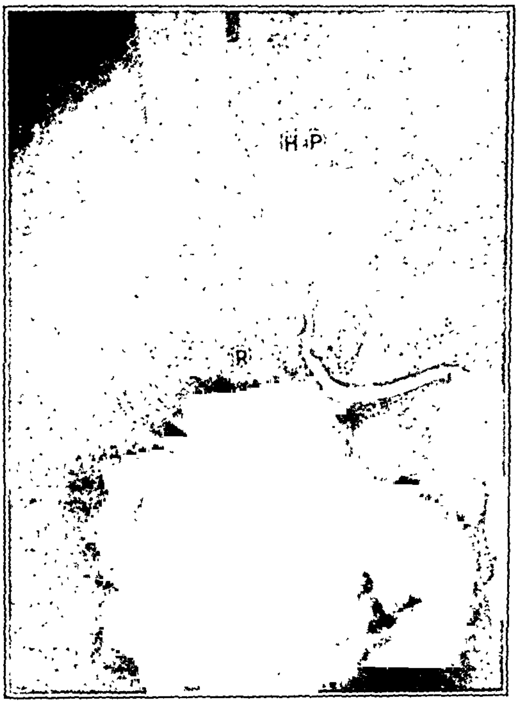

Fig. 3.—H.P., aged 5. This patient had obstruction at the vesical neck and left ureteral reflux which destroyed the kidney and required nephrectomy. A cystotomy was also done and a hypertrophied internal sphincter was resected.

ROENTGENOGRAPHIC ANATOMY OF THE MALE URETHRA

The entire urethra is outlined, including the base of the bladder. In the relaxed state on the anteroposterior view in the child, the bladder is spherical or elliptic, and the base, which lies well above the level of the upper border of the symphysis, is flattened or slightly convex, with the convexity downward. In the contracted state, the bladder assumes a more rounded form, being elongated vertically and narrowed horizontally, and the base is about 1 cm. lower.

The prostatic portion of the urethra lies in the midline behind the symphysis pubis; it begins at the base of the bladder and terminates at the external sphincter. The proximal narrowed portion represents the internal sphincter, and the distal portion the external sphincter. On voiding, the descent of the detrusor retracts the posterior lip of the vesical neck and the internal sphincter appears on the urethrogram shaped like an inverted cone. In the widest portion of the prostatic urethra is an ovoid area of increased radiance produced by the elevation of the verumontanum. This structure is best visualized on the retrograde urethrogram. The length of the prostatic urethra, the supracollicular portion, and the seminal colliculus varies with age (the table).

The membranous portion of the urethra is wedge shaped, with the apex at the external sphincter. The distal portion terminates at the bulb, but its boundaries are ill defined.

---

[7] Brodny, M. L.: A New Instrument for Urethrography in the Male, J. Urol. 46: 350, 1941.

[8] The Clay-Adams Company, New York, gave technical assistance and supplied this tip.

The bulb is the widest portion of the urethra. In the anteroposterior view, it is spherical in shape and casts a denser shadow than the rest of the urethra owing to the penoscrotal curve, which causes overlapping in this view.

The anterior part of the urethra is visualized in its entirety on the oblique view. The outline is regular and narrows distally to the meatus.

COMMENT

The limitations of space forbid the presentation of a complete series of urethrocystograms illustrating every condition that can be diagnosed by this procedure. For purposes of discussion, the major pathologic conditions for which urethrocystographic examination is of value in the male child have been classified in five groups: congenital anomalies, obstructive uropathies, infections, neuromuscular dysfunction and control of surgical status. Pertinent examples of each group are presented, and sufficient data and description are introduced to appraise the value of the procedure.

[illegible] *Congenital Anomalies.*—Forty per cent of all the anomalies of the body occur in the urogenital tract, [illegible] a third of these are urologic problems. Anomalies [illegible] the lower portion of the urinary tract are especially important in the pediatric patient, since they may lead to bilateral renal destruction if they are of the obstructive type. Therefore, early diagnosis and correction of the lesion before permanent damage occurs is often life saving.

It is recognized that more than one anomaly may occur in the same patient, and complete and thorough investigation is indicated even in the presence of obvious external lesions. Urethrography in hypospadias has disclosed, for example, additional lesions such as atonicity of the bladder and internal sphincter secondary to a spina bifida occulta. Urethroscopy in many of these patients is often difficult and inconclusive. The visualization of the type and extent of accessory urethral canals is best accomplished by the roentgenologic method.

Valves of the posterior urethra are serious congenital lesions which not infrequently occur in children. Obstruction is produced in the prostatic urethra by mucosal folds which distend into cusps and retard or obstruct the urinary flow. These can be visualized on the retrograde and voiding urethrogram and appear as a balloon-like dilatation of the supracollicular portion of the urethra. The typical effect of back pressure due to infravesical obstruction is found proximal to the valves.

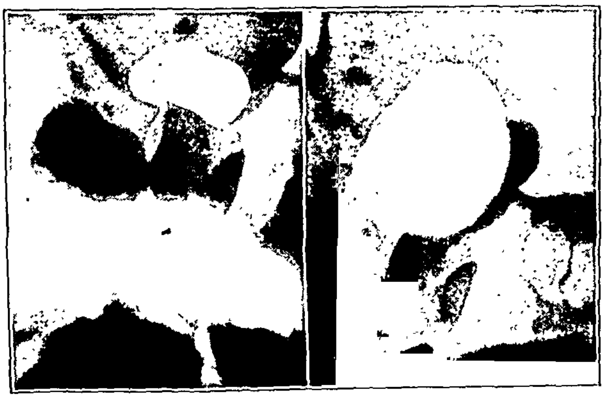

Fig. 4.—M.S., aged 9. Median bar obstruction. Right, voiding method, oblique view. Left, retrograde method, oblique view. Note the rigidity of the vesical neck and the notching of the posterior lip.

The value of urethrocystography is illustrated in the case of a boy aged 9 years. This patient was seen on April 4, 1945, with a history of nocturnal and diurnal incontinence since birth. He was one of twins; the other twin appeared much healthier and did not have any urinary symptoms. Local physical examination revealed no significant abnormality except for a pinpoint urethral meatus. The urethrographic findings are shown in figure 2. The presence of a valve in the posterior part of the urethra was verified by cystoscopy two days later. We have encountered 3 other patients with congenital valves, in 1 of whom serious renal damage and renal rickets developed. This case has been previously reported in detail.[9]

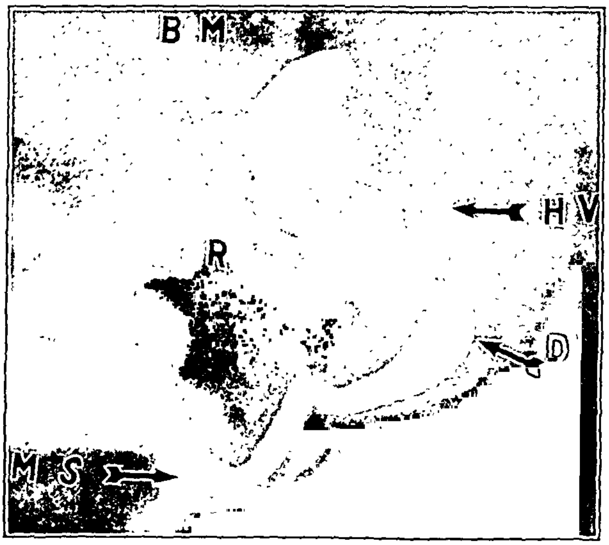

Fig. 5.—Patient B.M. *M.S.*, meatal stricture. *D.*, dilated bulbous urethra. *H.V.*, hypertrophic verumontanum. The triangular appearance of the vesical neck is consistent with hypertrophy.

Urethrocystography is also of value in the study of pseudohermaphrodism, congenital urethral fistula, diverticulum of the urethra and reduplication of the urethra.

2. *Obstructive Uropathies.*—The importance of early recognition of obstruction of the lower portion of the urinary tract in children cannot be too forcefully emphasized. Mechanical interference with voiding causes stasis, back pressure, infection and ultimately destruction of tissue. The prognosis is dependent on the extent of permanent renal damage produced by these factors. Roentgenography will materially aid early diagnosis.

Various types of congenital and acquired lesions occur at the vesical neck that can be diagnosed by urethrocystography. Changes in the architecture of the posterior part of the urethra in relation to the base of the bladder may be recognized. From roentgenographic studies, the details of the anatomic relationship of the urethra, the prostate and the base of the bladder can be determined, and also physiologic information can be obtained as to the tone of the bladder wall, the sphincters and the detrusor mechanism.

The cystogram in these obstructions reveals thickening of the bladder wall and irregularity of the vesical outline. The trabeculations, saccules or diverticula that may appear are similar to those caused by obstruction in the adult bladder.

In hypertrophy of the internal sphincter, the supracollicular portion of the urethra is elonga[illegible]d comressed, forming a collar-like deformity which projects nto the bladder and elevates and makes concave the utline of the base (fig. 3). In contracture of the vesical eck, the region of the internal sphincter is shortened nd constricted and the base of the bladder is flattened.)n the voiding urethrogram, the supracollicular portion f the urethra fails to dilate entirely owing to the igidity of the vesical neck, which appears triangular n shape. Median bar hypertrophy is best recognized n the oblique view and appears as a notching and elevaion of the posterior lip at the urethrovesical junction, esulting in angulation of the channel in an anteroosterior direction. On the voiding urethrogram, there s a barlike projection of the posterior urethral wall t the vesical neck (fig. 4).

---

[9] Derow, H. A., and Brodny, M. L.: Congenit[illegible] Urethr[illegible] Valve Causing Renal Rickets, New England J. Med. [illegible] 1939.

Strictures of the urethra may be congenital, inflamnatory or traumatic in origin, and they may be single or nultiple. Urethrocystography will demonstrate their ype, location and number, the degree of obstruction nd the response to treatment. The small caliber of the anal in children makes routine urethroscopy difficult nd unsatisfactory.

Stricture of the external meatus is the most frequent onstriction of the urethra in the pediatric patient and nay be associated with anomalies of the urethra such s hypospadias or epispadias. However, the majority f strictures are secondary to excoriation of the external rifice in infancy. These ulcerations form a scar which ncircles the meatus and eventually contracts and gives ise to stenosis. This condition is commonly found n persons subject to enuresis and can be demonstrated n the urethrogram (fig. 5). On the voiding urethrogram, the canal is usually considerably dilated from the ladder to the meatus, and the cystogram may show rabeculation or even sacculation.

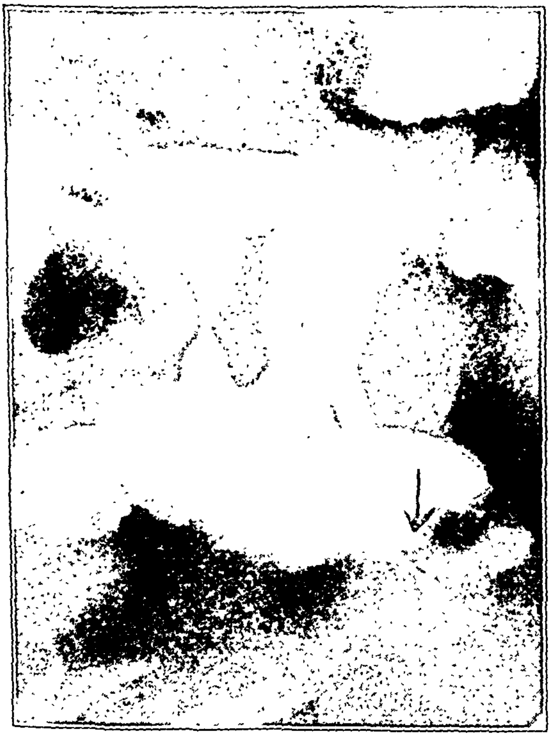

Fig. 6.—The arrow points to narrowing of the fossa navicularis. Note ronounced widening of the anterior portion of the urethra. The verumonmum is enlarged and the bladder is atonic.

Constriction or narrowing of the navicular portion of the urethra is usually congenital in origin, and the length of the urethra affected varies (fig. 6). The seminal colliculum is a common site of pathologic change in children and is well visualized on the urethrogram. The normal seminal colliculum appears as an elliptic area of diminished density in the midportion of the prostatic urethra, and its size varies with the age of the patient. Hypertrophy of this area may be congenital and at times causes obstruction. Congestion and infection associated with prostatitis may cause enlargement of the seminal colliculum, which may increase to two to three times its normal size and become round or pyriform in shape. Polyps, cysts and edema produce characteristic images on the roentgenogram. Occasionally the seminal colliculum is not visualized, and its absence may be a congenital anomaly or be due to hormonal disturbances.

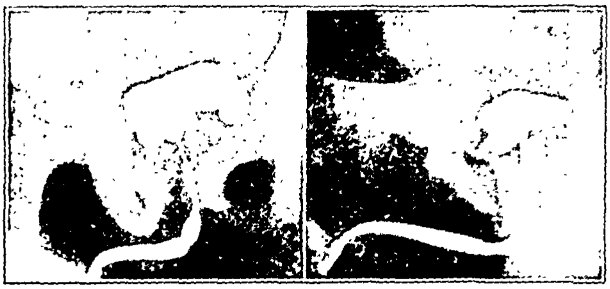

Fig. 7.—Patient aged 12, with prostatitis. Note the presence of a budlike projection resembling a saccule in the region of the verumontanum. This represents a dilated prostatic duct.

3. *Infections.*—We have found roentgenographic and cystoscopic evidence of chronic infection of the bladder in many children with negative urinary findings. The absence of pus or organisms in the urine sediment in routine examination does not always rule out inflammatory changes. Cystitis is always secondary to infection of the upper or lower portion of the urinary tract.

The cystogram in acute cystitis shows a spastic contracted bladder with irregular fuzzy borders due to edema. On the voiding urethrocystogram, thickening of the bladder wall, increase of the bladder contraction and spasticity of the lumen of the posterior part of the urethra and external sphincter can be observed.

Chronic cystitis in children is often an insidious disease and may be associated with infravesical obstruction or neuromuscular imbalance. The cystogram in mild infections of the bladder does not differ from the normal. In infections of long standing, the capacity of the bladder is diminished and the outline is fuzzy or slightly irregular.

Urethritis in the young male may be nonspecific and secondary to urethral meatitis, balanoposthitis, phimosis, foreign body irritation or abnormal masturbation, or it may be due to a gonorrheal infection following sexual contact. Urethrocystography is chiefly of value in patients in whom infection persists or recurs. The picture will help disclose urethral obstruction, congenital anomalies and the presence of complications. The anatomic changes caused by infection in the anterior part of the urethra appear on the roentgenogram as a narrow canal with a fuzzy outline. Following constant drainage of the bladder by a catheter, the urethrogram may present a bizarre appearance caused by edema and infection.

Prostatitis in the young may be idiopathic, hematogenous in origin or a complication of urethral or vesical infection. Elevation of the base of the bladder, enlargement or elongation of the seminal colliculum and slight compression and narrowing of the prostatic urethra are typical findings on the urethrogram. Since rectal examination and prostatic massage may be unsatisfactory in the young male, roentgenographic investigation is of value, as illustrated by the following case.

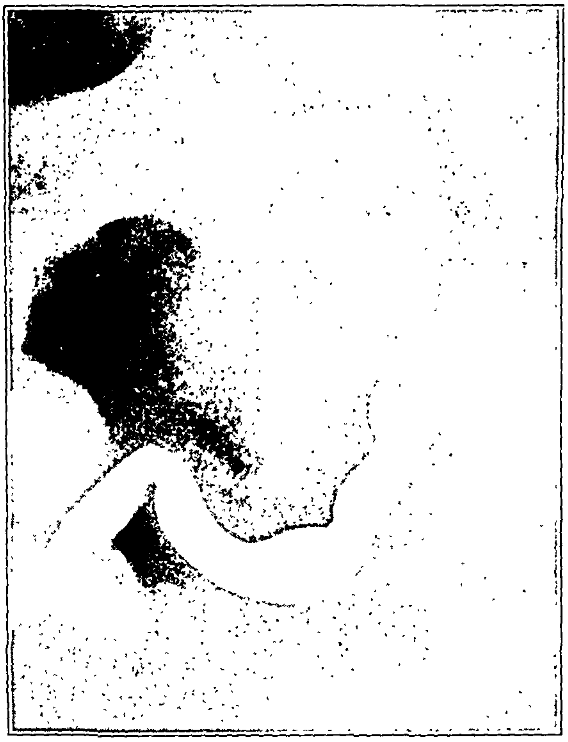

Fig. 8.—Urethrocystogram. Neurogenic bladder and urethra, spastic type. Bladder contracted and trabeculated. The internal sphincter is relaxed and the posterior part of the urethra is considerably widened.

A boy aged 12 complained of frequency and burning of one week's duration. Local physical examination was negative. The sediment of the urine was not remarkable. Attempt at prostatic examination was unsatisfactory, and a urethrogram was taken (fig. 7). Subsequent rectal examination confirmed the diagnosis of prostatitis. The normal prostatic ducts are not outlined on the urethrogram. Infected ducts are readily filled with opaque medium owing to inflammatory changes causing dilatation and loss of tone. These ducts appear as elongated, linear or budlike projections radiating from the region of the utricle.

Excessive masturbation causes chronic congestion of the prostate and characteristic changes on the urethrogram. The lateral lobes project into the bladder, distorting and elevating its base and producing a pressure defect. There may be compression, elongation of the prostatic urethra and enlargement of the seminal colliculum.

4. *Neuromuscular Dysfunction.*—Neuromuscular vesical and urethral disturbances may be congenital or acquired. Early recognition of the etiologic factors and the underlying pathologic changes is necessary for proper treatment. Many of these young patients have long-standing histories of enuresis or chronic urinary infection.

Neuromuscular vesical disturbances vary in the degree and extent of involvement. The bladder may be atonic or hypertonic, smooth or trabeculated; the sphincters may be relaxed or spastic; the ureteral orifices may function properly or permit regurgitation. The cystogram and urethrogram localize the involved muscular components. The presence of infection may modify the roentgenographic picture.

The urethrocystographic examination in the spastic type of dysfunction shows a small and scalloped bladder, which is due to thickening of the bladder wall and exaggeration of the vesical rugae. The sphincters are contracted, and the entire picture is one of attempted expulsion of the mediums (fig. 8).

The cystogram in the atonic type of dysfunction shows an enlarged bladder, which may fill the entire pelvis or may extend beyond. The outline is smooth and regular. There may be a pouching of the base, roof or lateral recesses of the bladder. The vesical neck is not delineated on the cystogram, but if the internal sphincter is relaxed, the opaque medium leaks into the posterior urethra producing a funneled appearance. On the voiding urethrogram, the shape of the bladder changes little during expulsion of its contents owing to lack of muscle tonus. The changes in the urethra are primarily confined to the supracollicular portion, which is dilated because of atonicity (fig. 9). There may be a generalized dilatation of the remainder of the urethra.

5. *Control of Surgical Status.*—Urethrocystography not only will uncover pathologic changes which require surgical intervention, but is valuable for recording the anatomic and functional status following surgical treatment of the lower part of the urinary tract. The ease, simplicity and safety of the procedure permit frequent examination of the postoperative condition and aid in establishing the causes of unsatisfactory results. The procedure has been utilized postoperatively in children to check the results of urethrotomy, closed and opened

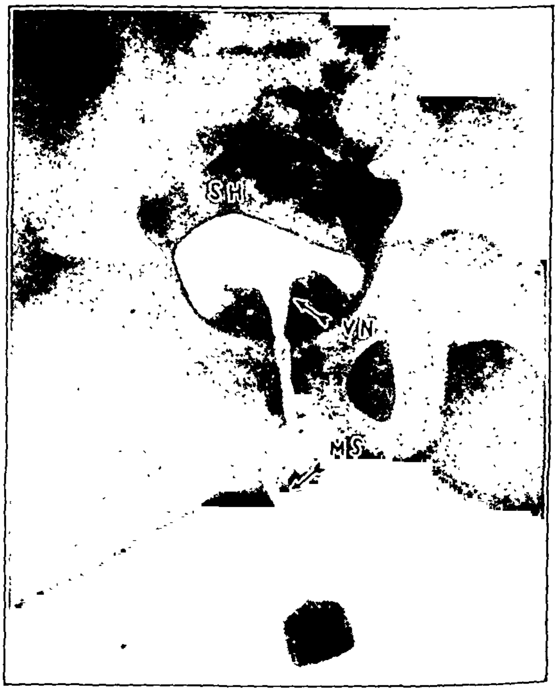

Fig. 9.—S.H., aged 10, experienced dysuria, frequency and burning for several months. An intravenous pyelogram was normal. There is moderate relaxation of the internal sphincter. The verumontanum is elongated and there is a narrowing at the external urethral meatus.

resection of the vesical neck, repair of hypospadias and epispadias, desiccation of urethral valves, polyps and cysts of the seminal colliculum, removal of urethral diverticulum and closure of urethral and vesical fistulas. Roentgenographic studies will determine the rate of recovery of the vesical tonus in the infant and child following chronic overdistention secondary to urethral obstruction, with or without infection, the persistence of ureteral reflux or the recovery of the internal sphincter following resection.

Urethrocystography in young children plays an important role in the diagnosis of trauma and foreign bodies in the lower part of the urinary tract, since a reliable history is not always available.

SUMMARY AND CONCLUSIONS

Methods of roentgenographic studies of the male urethra and bladder in children are described. "Rayopake," a *new* contrast medium, has been introduced for urethrocystography in children. A special instrument designed for urethrography in the adult has been adapted for children by the use of a small metal tip. The complete roentgenographic study of the urethra and bladder in children often requires the use of the voiding and retrograde methods. A technic of obtaining voiding urethrograms following intravenous pyelography in children has been described and is recommended as a routine procedure. A nonopaque plastic receptacle to facilitate voiding urethrography has been introduced.

It is possible by roentgenographic studies to visualize many of the anatomic changes and to interpret some of the urinary dysfunctions produced by diseases of the urethra and bladder.

Urethrocystography is valuable for studying the end results of operative therapy of the lower part of the urinary tract.

The usefulness of roentgenographic examination of the bladder and urethra in children will increase as experience is gained in the correct interpretation. This requires extensive correlation of the roentgen observations with cystoscopic, operative and postmortem studies.

Urethrocystography is an innocuous procedure which merits general adaptation for the study of the lower part of the urinary tract in pediatric patients.

636 Beacon Street.

ABSTRACT OF DISCUSSION

Dr. Monroe E. Greenberger, New York: The paper emphasizes phases of our specialty in which the general urologist shows an inadequate interest. Most of us lack an abundant experience in pediatric urology and in our interpretations of roentgenographic observations on the distal part of the urinary tract we are not as definite in our opinions as we may, for example, be about calyceal distortions. Judging from the excellent illustrations, the new opaque medium, "rayopake," introduced by Dr. Brodny, promises to be extremely useful in delineation of the lower part of the urinary tract. It is often difficult to conduct a study on children involving manipulative procedures without the use of anesthesia. Dr. Brodny is to be commended for his apparent facility in overcoming the obstacle. No doubt his instrument for urethrography in the male has made this possible. We have had increased success in obtaining cooperation from some of our younger patients by delaying any type of instrumental study, even simple passage of a small catheter, until several visits have established a warm, trusting relationship. The possibility of psychic trauma in certain children of an age group likely to be sensitive concerning treatment of external genitalia must be considered. Occasionally, it may be advisable to forego the advantages of study without anesthesia to spare condemnation from some psychoanalyst at a late date, as the early source of the development of a sexual neurosis. Dr. Brodny's suggestion of obtaining urethrograms following intravenous pyelography is especially appealing, and we may well consider it as a supplement to our usual routine in adults as well as children. The discussion of various types of disorders of the lower part of the urinary tract visualized by roentgenographic study has been excellent and informative, but one cannot be too dogmatic about interpretation, particularly about verumontanum shadows. How often do we have a definitely similar inflammatory syndrome in the posterior part of the urethra in persons who present several varying degrees of pathologic change in the verumontanum ranging from pale atrophy to an intense congestion and enlargement. We all agree that increased experience and correlation with other types of clinical investigations will enhance the value of cystourethrography.

Dr. M. Leopold Brodny, Boston: There are two points I wish to make. One is that we must not be discouraged with *the interpretation of urethrograms. It takes practice and* requires some correlation with the cystoscopic findings. When we first started out, we had to do many of these procedures, see what we found cystoscopically and see what we found at the time of operation. The interpretation is not always correct, not any more than interpretation of pyelograms is always correct. But we believe that, if an effort is made, the procedure will be found extremely valuable and as accurate as pyelograms are for the diagnosis of renal pathologic change. I want to pay tribute to my co-worker, Dr. Robins, who is a roentgenologist. I feel that this type of work must be done in the form of a cooperative study, because the point of view of the urologist and that of the roentgenologist add ideas and information which are valuable for this type of work.

NEWER REPOSITORY PENICILLIN PRODUCTS

E. W. THOMAS, M.D.

Buckwalter and Dickison[1] recently reported a new repository type of penicillin product.[2] They introduced the principle of suspending penicillin salts in peanut oil gelled with aluminum stearates, water repellent substances. They compared the absorption-delaying properties of this vehicle with the conventional repository vehicles in animals. The study recorded here was designed to carry this comparison further—in human subjects.

The facilities of four assay laboratories were used, and assays were performed by two different methods, a modified Rammelkamp method and a cup plate procedure employing Sarcina lutea. Control samples of blood were drawn before the injection; each patient then received 300,000 units of penicillin in repository form, and consecutive samples of blood were taken at the intervals indicated on the chart. The lines on the chart are the lines fitted by the method of least squares to the logarithm of the average blood concentration with time in hours.

Messrs. Brumbaugh, Noel and Crutchfield of Bristol Laboratories, Inc., made the statistical analysis of these data.

From Bellevue Hospital and New York University College of Medicine, New York (Drs. Thomas and Rein); Syracuse University Hospital, Syracuse, N. Y. (Dr. Lyons); Antibiotic Section Laboratory Walter Reed General Hospital and George Washington University Hospital Department of Medicine, Washington, D. C. (Dr. Romansky), and Bristol Laboratories Inc., New York (Dr. Kitchen).

[2] "Flo-cillin," supplied by Bristol Laboratories, Inc.

Table 1 presents, in accordance with standard practice,[3] the percentages for all patients whose blood concentrations were 0.03 unit per cubic centimeter, or above, at the indicated hours for the various products studied. It also shows the total number of patients whose blood samples were assayed and the average concentration of penicillin per cubic centimeter of serum at these various intervals.

Table 3 shows the number of lots of each product tested and the percentage of particles of each product above or below a diameter of 50 microns on a relative weight basis.

The results obtained by a single injection indicated that the gelled product warranted a series of observations following its prolonged use.

Table 2 exhibits blood concentrations following prolonged administration of procaine penicillin in oil gelled with 2 per cent aluminum monostearate (large particle). Sixteen patients received injections once daily for sixteen days, and blood levels were determined at

A., and Eagle, H.: Serum Concentrations of Penicillin G in Man Following Intramuscular Injection in Aqueous Solution and in Peanut Oil-Beeswax Suspension, Am. J. Med. 4: 343 (March) 1948.

regular intervals for the first twenty-four hours and at twenty-four hour intervals thereafter until the concentration fell below 0.039 unit per cubic centimeter following the last injection. The purpose of this study was twofold: (1) to observe any untoward effects of repeated injection and (2) to record maintenance of high blood concentrations.

TABLE 3.—*Number of Lots of Each Product Tested and Percentage of Particles Above or Below 50 Microns in Diameter*

Product	No. of Lots	Particle Size*
A. Sodium penicillin G in peanut oil with 4.8% (w/v) white wax	1	57% over 50 microns
B. Sodium penicillin G in peanut oil with 2% (w/v) aluminum monostearate	1	50% over 50 microns
C. Procaine penicillin G in oil............	3	78.5% over 50 microns
D. Procaine penicillin G in peanut oil with 2% (w/v) aluminum monostearate (large particle)	3	93% over 50 microns
E. Aluminum penicillin in peanut oil with 2% (w/v) aluminum monostearate	2	70% over 50 microns
F. Procaine penicillin G in peanut oil with 2% (w/v) aluminum monostearate (small particle)	5	95% under 5 microns

* Chandler, V. L.; Romansky, M. J.; Welch, H.; Robinson, J. A.; Zeller, W. M.; Dowling, H. F., and Hirsch, H. L., A Method of Determining the Size and Relative Weight of Penicillin Particles and Its Importance in Preparing Adequate Preparations of Liquid Penicillin in Oil and Wax, J. Am. Pharm. (Scient. Ed.) 37: 21 (Jan.) 1948.

COMMENT AND SUMMARY

The absorption of all salts of penicillin tested was delayed longer in the aluminum monostearate in peanut oil gel than when the same salts were suspended in peanut oil alone or in peanut oil plus wax. Further, it is of particular interest to note that procaine penicillin in peanut oil gelled with 2 per cent aluminum monostearate of a small particle size maintained a blood concentration over a much longer period than the same combination but with large-sized particle penicillin. No instance of undue irritation or untoward effects were reported by or observed in any of the subjects receiving the aluminum monostearate in peanut oil gelled products other than the occasional allergic reactions to penicillin. The influence of particle size, *per se*, on the maintenance of blood concentration will be reported later by Buckwalter, Dickison and this group.

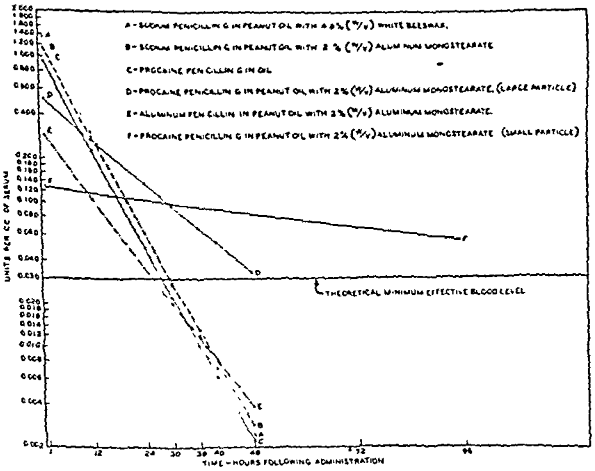

Chart of average concentrations of penicillin in the blood produced with single injections (300,000 units each) of six repository penicillin preparations (Sarcina lutea technic).

MORTALITY OF MEDICAL SPECIALISTS, 1938-1942

LOUIS I. DUBLIN, PH.D.
and
MORTIMER SPIEGELMAN, F. A. S.
New York

The growth of specialization in the practice of medicine has reached a point where it may well be asked, first, whether the mortality of physicians so engaged differs from that of physicians in general practice and, second, what differences in mortality there may be among the several specialties. The answers to these questions may be determined from an analysis of the records used for an earlier study in which the mortality of all American physicians during the period 1938-1942 was compared with that of the general population.[1]

For the purposes of the present investigation, only physicians devoting full time to their specialty were considered as specialists, in accord with the following excerpt from the American Medical Directory (sixteenth edition, 1940):

> A symbol designating specialty practice is entered on request whenever the physician is (1) a member of a constituent state association, (2) a member of a special national or interstate society, the membership of which is listed in the Directory, or (3) a professor, an associate or assistant professor in an approved medical school. ..When the abbreviation designating a specialty is followed by a star (★) it indicates that the physician claims his practice is limited to that particular branch of medicine...This information concerning specialty practice is based only on personal data furnished by the physician.

This study thus excludes from the specialties those physicians who state an interest in some branch, but do not limit their practice to it.

SOURCES OF DATA

This study is based on a tabulation of full time medical specialists listed in the American Medical Directory of 1940[2] and the deaths among corresponding specialists within the five year period from 1938 to 1942. The data relate only to physicians residing within the United States.

The distribution of the living physicians in 1940 according to their specialty is shown in table 1. Of the 175,176 physicians listed in the Directory, 37,010, or 21.1 per cent of the total, claimed to be full time specialists. Largest in number was the group made up of ophthalmologists, otologists, laryngologists and rhinologists, of whom there were 7,636; these constituted 4.4 per cent of all

[2] The numbers of living physicians according to their specialty and year of birth, but without distinction by sex, were tabulated from the American Medical *Directory* for 1940 by the States Relations Division of the United States Public Health Service. The results of these tabulations were made available through the cooperation of Mr. Elliott H. Pennell.

physicians and 20.6 per cent of all specialists. Next in rank were those practicing internal medicine, numbering 6,466; these were 3.7 per cent of all physicians and 17.5 per cent of the specialists. Third in rank were the surgeons, of whom there were 5,892, or 3.4 per cent of all physicians and 15.9 per cent of the specialists. Obstetricians and gynecologists ranked fourth, with 2,553 members. Each of the remaining specialties listed in table 1 had less than 2,500 physicians who gave it their full time.

TABLE 1.—*Medical Specialists Listed in the Directory of the American Medical Association, 1940*

Specialty	Number	Percentage of All Physicians	Percentage of All Specialists
All physicians	175,146	100.0

Bacteriology	64	*	0.2
Others, not specialists	138,136	78.9	

*Less than 0.05.

The average ages and the age distributions of all physicians, of the full time specialists, and of those not full time specialists, as derived from the American Medical Directory of 1940, are set forth in table 2. In this and subsequent tables, specialists in internal medicine and pediatrics were classed together in one group, since both practice under essentially similar conditions, and another group was formed of the surgical specialties, namely, orthopedic surgeons, proctologists, urologists and industrial surgeons.

TABLE 2.—*Average Age and Percentage Distribution According to Age of Medical Specialists Living in 1940*

Specialty	Average Age	Percentage Distribution According to Age (All Ages 100%) Under 35	35-44	45-54	55-64	65-74	75 and over
All physicians	47.6	26.1	22.3	18.2	18.0	11.6	3.8

Dermatology	47.2	10.8	35.9	28.3	15.9	7.7	1.4
Pathology	47.3	9.5	34.3	31.8	17.8	6.0	0.6
Public health	48.2	18.6	27.5	19.4	20.5	12.7	1.3
Tuberculosis	48.6	8.8	32.1	28.8	21.6	7.3	1.4
Bacteriology	48.3	9.4	42.2	17.2	20.3	10.9	-
Others, not specialists	47.4	30.5	19.8	15.4	17.5	12.3	4.5

The average age of all specialists was 48.5 years, one year greater than that for the nonspecialists. Surgeons, with an average age of 49.4 years, were the oldest on the list, and obstetricians and gynecologists were the youngest, with an average of 46.4 years. Whereas 30.5 per cent of the physicians not specialists were under 35 years of age, only 9.9 per cent of the specialists fell within this age period. This contrast is a natural consequence of the time taken to acquire training and experience before one can become a specialist. The proportions of specialists under age 35 were smallest among surgeons and the group constituting ophthalmologists, laryngologists and rhinologists. On the other hand, the proportions under 35 were largest for anesthetists and public health physicians. Since specialization is a comparatively recent development, and, further, since the specialists are, by definition, those who devote their full time to their interest, it is not suprising to find only 1.2 per cent of them at age 75 and over. Among those not specialists, 4.5 per cent were included in this terminal age group. Because of the concentration of medical specialists within the age range from 35 to 74 years, the study was confined to this period of life. Although the proportion of specialists under age 35 is not negligible, it was considered advisable to omit them from the study, since they had not been exposed long enough to manifest the effects of any hazards that may be involved in the practice of a specialty. Besides, the number of deaths among specialists under age 35 was too small for study.

There were altogether 12,419 deaths of physicians at ages 35 to 74 years during 1938-1942 that entered into the earlier study. The full time specialists among them were located by referring to the latest issue of the American Medical Directory in which the name of the deceased was listed and noting the specialty claimed at that time. Most of the names of those dying in 1940, 1941 and 1942

were found in the 1940 Directory; for deaths in 1938, 1939 and later years not found in the 1940 Directory, reference was made to the 1938 Directory. In a few instances it was necessary to look into the 1936 Directory. In order to ascertain whether any bias was introduced by the use of three Directories, the deaths within each specialty were tabulated according to the year of occurrence; the scatter of the numbers left no ground for suspicion on this score.

The search just described yielded a total of 2,029 deaths of specialists at ages 35 to 74 years for the period 1938-1942; this number was 16.3 per cent of deaths of all physicians of the same ages. The distribution of the deaths from the principal causes according to the specialty of the deceased is shown in table 3. Only 23, or 1.1 per cent of the 2,029 deaths of specialists, were women. In view of this situation, it was not considered necessary to distinguish sex in studying the mortality of the specialists.

METHOD OF PROCEDURE

As a basis for comparison of mortality of specialists and nonspecialists, and also among the several specialties, the death rates according to age and cause of death for all male physicians from the earlier study of 1938-1942[3] were taken as the standard. For each specialty, the ratio was formed of the actual deaths from a specific cause to the number that specialty would have experienced if it had been subject to the death rates of the standard thus chosen.[4] For convenience the ratio found in this way will be referred to hereafter as the mortality ratio. The results of such a computation for all specialties combined are compared, in table 4, with the corresponding results for physicians who are not specialists. An asterisk following a mortality ratio indicates significance in the statistical sense, that is, the probability is less than 5 in 100 that a deviation of the actual from the expected deaths at least as great as that observed is a chance occurrence.

MORTALITY OF ALL SPECIALISTS

Taken as a group, the mortality of specialists at ages 35 to 74 years is only 78 per cent of the standard, while that of the nonspecialists at the same ages is 110 per cent of the standard. The advantage of the specialists is somewhat greater for those below age 55, for whom the mortality ratio is 74 per cent, than for those over that age, the ratio here being 80 per cent. Each of the specialty groups studied had a lower mortality than the nonspecialists (table 5).

TABLE 4.— *Mortality According to Cause of Death Among All Specialists and Others, Not Specialists, at Ages 35-74: Ratio of Actual Deaths to the Deaths Expected on the Basis of Age-Specific Death Rates for All Male Physicians, 1938-1942*

Cause of Death	Mortality Ratio: All Specialists	Mortality Ratio: Others, Not Specialists	Actual Deaths: All Specialists	Actual Deaths: Others, Not Specialists

* Significant in the statistical sense, that is, the probability is less than 5 in 100 that a deviation of the actual deaths from the expected deaths at least as great as that observed is a chance occurrence.
+ From 5 to 9 actual deaths entered the computation of this ratio.
† Less than 5 actual deaths were recorded in this category.
⊕ No deaths were recorded in this category.

There may be several factors contributing to this generally favorable situation among specialists. In the first place, some self selection may be exercised on the part of those entering a specialty; a certain degree

---

3. For death rates in broad age groups for several causes of death, see Dublin, L. I.· Spiegelman, M., and Leland, R. G.: Longevity and Mortality of Physicians, Postgrad. M. I. 3:183 (Sept.) 1947. The detailed death rates used as the standard have not yet been published.

4. This computation was carried out separately for each five year age group, as 35-39 and 40-44. The first step was to obtain, for each specialty, an age distribution of physicians exposed to the risk of death. The following example shows how this was derived from the basic tabulation.[2] Thus, the number living at age 40 in each year of the period 1938-1942 is made up, in close approximation, of those listed in the Directory of 1940 as having been born in the period 1898-1902. A similar procedure was followed to obtain the number living at each age from 41 to 44 years, the sum of all these numbers yielding the total physicians in a specialty at ages 40 to 44 years exposed to risk of death during 1938-1942. For each five year age group, the number exposed to risk of death was multiplied by the corresponding death rate of the standard to obtain the expected deaths. The expected deaths were then summed for ages 35 to 74 years and compared with the actual number of deaths for the same broad age group.

of physical well-being is required to continue studies over an extended period of years. Then, the specialists, who on the whole undoubtedly have a larger income than the nonspecialists, may be in a better position to take care of themselves by more frequent and longer vacations when in health and by superior medical care when ill. The specialists, who are concentrated in urban centers, have a further advantage in their medical care from their accessibility to large hospital facilities and opportunities to consult with other specialists.

Over three fifths of the deaths of specialists at ages 35 to 74 years are from the cardiovascular-renal diseases, and their mortality ratio from these conditions is 81 per cent, practically at the same level as for all causes of death. A corresponding similarity is seen, in table 5, for almost all of the classes of specialists considered, as well as for nonspecialists.

For two of the important causes of death, cancer and diseases of the coronary arteries and angina pectoris, the mortality of specialists, as a unit, is not much better then that of the nonspecialists. In the case of diseases of the coronary arteries and angina pectoris, the mortality ratio of specialists is 97 per cent and that of nonspecialists 102 per cent. Thus, the advantage specialists have with regard to over-all mortality hardly exists at all as far as coronary disease is concerned. Apparently, whatever benefits specialization may bring, they are not great enough to overcome the tensions of medical practice in general. In the earlier paper,[1] it was indicated that the high rate of mortality of physicians from coronary disease, as compared with the general population, may arise from causative factors, in addition to the opportunity for better diagnosis and reporting. There is, of course, also the possibility of differences in the quality of diagnosis and reporting of coronary disease between specialists and nonspecialists.

For cancer, the mortality ratios are 96 per cent among specialists and 109 per cent among nonspecialists. There is little variation from these ratios when cancers of the digestive organs, the respiratory organs and the genitourinary organs are considered separately. Evidently, both the specialist and nonspecialist are equally concerned in observing abnormal growth in themselves and, also, in seeking adequate treatment. Leukemia is practically identical in its incidence as a cause of death among specialists and nonspecialists.

Mortality from diseases of the prostate gland among the specialists is somewhat lower than the standard, the ratio here being 91 per cent as compared with 105 per cent for the nonspecialist; however, the numbers of deaths involved are too small to give significance to these results.

The record for specialists, as compared with nonspecialists, is particularly favorable in the case of the diseases of the respiratory tract and infectious diseases. Thus, the mortality ratio for pneumonia and influenza among specialists is only 61 per cent, while that for nonspecialists is 113 per cent. The higher mortality from these conditions among nonspecialists is in line with expectation, since they are, in general, the more likely to call at any time, irrespective of weather, and, further, they are more likely to be exposed to the risk of infection from patients. Tuberculosis among specialists, as a group, has less than half the incidence observed for nonspecialists, the mortality ratios being 56 per cent and 118 per cent, respectively. A somewhat similar situation is seen for syphilis. The low rate of mortality from these two conditions among the entire body of physicians in general was shown in the earlier study.

Specialists experience about the same low level of mortality from ulcer of the stomach or duodenum, from hernia and intestinal obstruction and from cirrhosis of the liver; for each of these, the mortality ratio for specialists is somewhat over 60 per cent of the standard, while that for nonspecialists is over 110 per cent of standard. The rate of mortality among specialists is also comparatively favorable in the cases of appendicitis and of biliary calculi and other diseases of the gallbladder, both with ratios of a little under 80 per cent. The low rate of mortality from diabetes mellitus among specialists, only 36 per cent of the standard as compared with 120 per cent for the nonspecialists, may reflect better opportunities among the former for the recognition and treatment of this condition.

Violent deaths are relatively less frequent among specialists than among nonspecialists. Thus, the specialists have a mortality ratio of 76 per cent of standard from suicide, 95 per cent from automobile accidents and only 54 per cent from other forms of accident. The corresponding ratios for the nonspecialists are about 110 per cent.

Within the group of specialists, some rather wide variations in mortality become evident when the individual specialties are examined with regard to cause of death. For this aspect of the study, attention will be confined largely to the principal causes of death, that is, the cardiovascular-renal diseases as a unit, diseases of the coronary arteries and angina pectoris, cancer, pneumonia and influenzas and accidents. The numbers of deaths are too small for examination in greater detail. Table 5 shows the mortality ratios from the leading causes of death in the various specialties.

SURGERY

The rate of mortality among surgeons is somewhat higher than the average for all specialists, but considerably lower than that for nonspecialists. The mortality ratio for all causes of death at ages 35 to 74 years is 81 per cent for general surgeons and 86 per cent for the class comprising orthopedic surgeons, proctologists, urologists and industrial surgeons; the corresponding ratio for all specialists is 78 per cent and for nonspecialists 110 per cent.

There is little difference in the reported mortality from the diseases of the coronary arteries and angina pectoris among surgeons and nonspecialists, the ratios being practically at 100 per cent of standard for each category. It is pertinent that the mortality ratio from cancer among general surgeons is only 81 per cent of the standard,[5] a figure appreciably lower than that for any other specialty.

ANESTHESIA

There were only 17 deaths of anesthetists recorded during 1938-1942. In view of their close working association with surgeons, a comparison of the experiences in these specialties is of some interest. The mortality ratio for anesthetists, 88 per cent of standard, is somewhat higher than that of general surgeons, but hardly different from that of the class made up of orthopedic surgeons, proctologists, urologists and industrial surgeons.

OBSTETRICS AND GYNECOLOGY

Obstetricians and gynecologists, with a mortality ratio 75 per cent of standard from all causes of death, have a slightly better record than the average for all specialists. The mortality ratio from diseases of the coronary arteries and angina pectoris among obstetricians and gynecologists, namely, 108 per cent, is not statistically significant.

OPHTHALMOLOGY, OTOLOGY, LARYNGOLOGY AND RHINOLOGY

The mortality experience of this group of specialists from all causes, and also from the cardiovascular-renal diseases, from diseases of the coronary arteries and from cancer is a little below the average for all specialists; the mortality ratio is 75 per cent for all causes and 78, 93 and 90 per cent, respectively, for the specific conditions mentioned. Their mortality ratio for pneumonia and influenza, 66 per cent, is practically at the average for all specialists, but the ratio for fatal accidents appears high, though still well below the average for nonspecialists.

INTERNAL MEDICINE AND PEDIATRICS

Internists and pediatricians have a particularly low mortality ratio for all causes of death, only 69 per cent of the standard. This advantage extends through each of the causes of death shown in table 5. Especially noteworthy is their relatively low rate of mortality from diseases of the coronary arteries, 81 per cent of the standard. This contrasts sharply with the higher mortality from coronary disease among surgeons, obstetricians and gynecologists and suggests the possibility that conditions of practice may influence its low incidence.

NEUROLOGY AND PSYCHIATRY

The mortality ratio for neurologists and psychiatrists, 83 per cent of standard, is only a little above the average for all specialists. Their mortality from diseases of the coronary arteries lies just on the level of the average for specialists. However, for some reason not evident, neurologists and psychiatrists in this experience have an exceptionally high mortality from cancer, the ratio being 155 per cent of the standard; for all specialists, the mortality ratio from cancer is 96 per cent, while that for nonspecialists is 109 per cent.

ROENTGENOLOGY AND RADIOLOGY

Although the mortality ratio for all causes for roentgenologists and radiologists, namely, 90 per cent, is below that for nonspecialists, it lies well above the average for all specialists. In the case of coronary disease and cancer, their mortality ratios, 110 per cent and 133 per cent, respectively, exceed those for the nonspecialists. The high mortality from cancer among roentgenologists and radiologists may be of special significance when viewed in conjunction with their mortality from leukemia. Five of the 95 deaths among roentgenologists and radiologists in this experience were from leukemia; no other specialty had as many or as high proportion of deaths from this cause. The 5 deaths due to leukemia recorded for roentgenologists and radiologists is several times the number expected on the basis of the mortality experience of all male physicians, the standard of comparison. Although roentgenologists and radiologists constituted only 4.3 per cent of the living specialists, they had one quarter of the deaths from leukemia among all specialists. The facts are indicative of an extra hazard to roentgenologists and radiologists that may arise from their exposure to dangerous radiation.[6]

DERMATOLOGY

The mortality situation among dermatologists resembles that of roentgenologists and radiologists in considerable degree. Mortality from all causes among dermatologists, with a ratio of 98 per cent, is practically the same as the standard. Their mortality ratio from diseases of the coronary arteries, 131 per cent, is greater than that for any other specialty and lies well above the ratio for nonspecialists. Although the mortality ratio for cancer among dermatologists, 158 per cent, is based on only 9 recorded deaths, its high level may carry the same significance here as for roentgenologists and radiologists. In the small number of deaths (60) from all causes among dermatologists, 2 were ascribed to leukemia. When cancer and leukemia are considered together, the mortality ratio of dermatologists rises to 180 per cent of the standard. This situation may be of some importance in view of the frequent exposure of dermatologists to roentgen rays.

---

[5] In this case, the probability is 11 in 100 that a deviation of actual from expected deaths at least as great as that observed is a chance occurrence.

[6] Henshaw, P. S., and Hawkins, J. W.: Incidence of Leukemia in Physicians, J. Nat. Cancer Inst. 4:339 (Feb.) 1944. Ulrich, H.: The Incidence of Leukemia in Radiologists, New England J. Med. 234:45 (Jan. 10) 1946.

PATHOLOGY

Pathologists are favored with a lower rate of mortality than any other group of specialists. Their mortality ratio from all causes of death was only 62 per cent of the standard; the ratio for coronary disease was 73 per cent, but this is based on only 10 deaths and is not statistically significant.

PUBLIC HEALTH

For physicians specializing in public health work, the mortality ratio is 83 per cent; this is only a little above the ratio for all specialists. However, their mortality ratio from coronary disease is relatively high, namely, 113 per cent, as compared with an average of 97 per cent for all specialists and 102 per cent for nonspecialists.

TUBERCULOSIS

Mortality among specialists in tuberculosis is higher than that for any other specialty, the ratio being 99 per cent of the standard. Notwithstanding their relatively poor situation among specialists, their record is somewhat better than that of nonspecialists. This is not the case, however, with regard to coronary disease, for which the mortality ratio for specialists in tuberculosis is 124 per cent. Since physicians with a personal history of tuberculosis often specialize in the disease, it is not surprising to see that this condition accounted for a higher rate of mortality than in any other specialty.

SUMMARY

Physicians of ages 35 to 74 years who died during 1938-1942 were classified according to full time specialty on the basis of the last report in the American Medical Directory. A corresponding distribution of the number of specialists exposed to the risk of death during the period of survey was derived from a tabulation made by the United States Public Health Service from the Medical Directory of 1940. From these data, it is seen that the rate of mortality of specialists, as a group, is only 70 per cent of that of nonspecialists. Although there are decided variations in the rates of mortality among the specialists, each of them made a better record than the nonspecialists.[7] The most favorable situation is seen among pathologists, whose rate of mortality is less than three fifths of that of the nonspecialists. Although the poorest record among the specialists is made by those in dermatology and tuberculosis, their rate of mortality is only nine-tenths that of the nonspecialists. The lower mortality of specialists may arise from the self selection on the part of the healthier physicians to continue their studies, from higher income levels, from more favorable conditions of work and from opportunities for better medical care.

For almost all of the specialists, the mortality ratios for the cardiovascular-renal diseases are not much different from the corresponding ratios for all causes of death.

The same high level of mortality from the diseases of the coronary arteries and angina pectoris runs through practically all classes of specialists and the nonspecialists. Only internists and pediatricians show a rate of mortality from these conditions that is significantly lower than the average for all physicians.

The rate of mortality from cancer among general surgeons is well below the record for any other specialty and also for nonspecialists. Their advantage in this regard may be a consequence of their training in early recognition of the condition and of their knowledge of the benefit of early treatment. On the other hand, roentgenologists, radiologists and dermatologists have a high rate of mortality from cancer and leukemia, far above that for nonspecialists; this situation among these specialties suggests strongly the effect of their exposure to dangerous radiations.

Specialists, as a group, have a much lower rate of mortality than nonspecialists from the diseases of the respiratory tract, and infectious conditions, such as tuberculosis, pneumonia, influenza and syphilis. The specialists also fare comparatively better than nonspecialists in their rate of mortality from ulcer of the stomach or duodenum, hernia and intestinal obstruction, cirrhosis of the liver, appendicitis and diseases of the gallbladder. Suicide, automobile accident fatalities, as well as fatalities from other types of accident, are relatively fewer among specialists than among nonspecialists.

---

[7] There are some instances in which the lower mortality ratios for the specialists fail to meet the standard of statistical significance prescribed earlier in this paper. These instances have not been mentioned specifically in the text, since they can be located by reference to tables 4 and 5. In cases in which such mortality ratios are based on small numbers of deaths, the observations are subject to confirmation by the accumulation of further experience.

Special Article

DIPHTHERIA MORTALITY IN LARGE CITIES OF THE UNITED STATES IN 1947

Twenty-Third Report

No review of the deaths from diphtheria in the large cities was prepared for 1943 and 1944, but the annual tabulation and analysis of data was renewed in 1945 and 1946. The procedure followed for the 1947 report is described in the review of typhoid mortality for these same cities.[1] A communication was addressed to the health officer of each of the cities requesting the number of deaths from diphtheria both among residents and among nonresidents reported in 1947. Whenever the local data was incomplete, an appropriate request was directed to the state health officer. Comment was sought on any special outbreak of diphtheria or change in age incidence and any special program to secure the protection of children against this disease. In calculating death rates, the 1940 census figures were used. Footnotes indicate corrections in rates for those cities for which the Bureau of the Census has prepared official estimates for years subsequent to 1940.

The practice of charging all deaths, both among residents and among nonresidents, against the individual city has been continued, with the inclusion of appropriate symbols similar to those employed in previous years. Such symbols indicate those cities in which either (1) all deaths from diphtheria were stated to be among nonresidents or (2) one third or more of such deaths were stated to be among nonresidents. Attention is directed to table 11, which lists forty cities (there were thirty-one in 1946) that record no deaths from diphtheria in 1947. In eleven additional cities (table 13) (Albany, N. Y., Atlanta, Ga., Charlotte, N. C., Fall River, Mass., Kansas City, Mo., Milwaukee, Nashville, Tenn., Omaha, Richmond, Va., Spokane, Wash., and Washington, D. C.,) it is stated that all deaths from diphtheria in 1947 were among nonresidents. In addition to the thirty-six cities (table 12) (there were twenty-seven in 1946) with no deaths from diphtheria or typhoid in 1947, eight cities (Albany, Charlotte, Fall River, Milwaukee, Nashville, Omaha, Spokane, Washington) report no deaths among residents from either cause.

The fourteen New England cities (table 1) (population 2,579,152) have failed during the past seven years to equal the low point of 6 deaths in 1940. The number of deaths in 1947 (15), however, is less than half that of the preceding year (36). The death rate for the group as a whole was 0.23 in 1940 and 0.58 in 1947 (1.40 in 1946). These cities find themselves in fifth place (they were in sixth place in 1946), the death rate being higher only in the Mountain and Pacific group (1.45), the East South Central group (1.31) and the West South Central group (1.02). In contrast to the 22 deaths (12 among nonresidents) which were recorded in Boston in 1946, in 1947 there occurred only 8 deaths (3 among nonresidents). Nine cities (Bridgeport, Conn., Cambridge, Mass., Hartford, Conn., Lowell, Mass., New Bedford, Mass., New Haven, Conn., Springfield, Mass., Worcester, Mass., and Waterbury, Mass.) record no death (there were only five such cities in 1946). It is stated that in Fall River the 1 death was among nonresidents. Of the 15 deaths in this group of cities, 4 were among nonresidents. While the number of deaths among residents has decreased from 19 in 1946 to 11 in 1947, the number of deaths among nonresidents has decreased from 17 in 1946 to only 4 in 1947. As these cities maintain a liberal policy with regard to hospitalizing patients from nearby communities, it is evident that such communities have not contributed so significantly to the problem of diphtheria in the larger cities. After a period of ten years with no death from diphtheria, Lynn, Mass., reports 1 among residents in 1947. It is stated that this death was of a single male office worker, aged 59. The cause of death was determined at autopsy. Waterbury records no death during the past nine years and Bridgeport none for eight years. Worcester reports for the past eight years only 2 deaths among residents (in 1946). New Haven records no death among residents for nine years. Lynn, after a period of ten years with no death from diphtheria or typhoid, relinquishes the place of honor (table 12) to Yonkers with no death from either cause for nine years (and Grand Rapids with no death for eight years). Bridgeport records no death from diphtheria or typhoid for six

[1] Typhoid in the large cities of the United States in 1947: Thirty-Fourth Report, to be published.

years and Waterbury none for four years. Providence, R. I., reports 4 deaths from diphtheria and Somerville, Mass., 1, all among residents.

The eighteen cities (population 13,129,185) in the Middle Atlantic states (table 2) continue to hold first place. The group rate of 0.24 is lower than that of 1946 (0.38), but double the rate of 1944 (0.11), when these cities set an all-time low for any group. In 1946 there were 50 deaths, 9 among nonresidents. In 1947 there were 32 deaths, 5 among nonresidents. Thus the number of resident deaths has decreased from 41 in 1946 to 27 in 1947. For 1947 eleven cities (there were eleven in 1946, twelve in 1945) appear on the honor list (table 11), with no death from diphtheria (Elizabeth, N. J., Erie, Pa., Jersey City, N. J., Newark, N. J., Paterson, N. J., Reading, Pa., Rochester, N. Y., Scranton, Pa., Syracuse, N. Y., Utica, N. Y., and Yonkers, N. Y.). Elizabeth reports no death for eleven years and heads the honor list (table 10), Yonkers none for ten years, Syracuse none for eight years, Paterson and Utica none for six years, Reading none for five years and Newark none for four years. Rochester reports only 1 death (in 1946) among residents during the past thirteen years. It is stated that no death from either typhoid or diphtheria has occurred in Yonkers during the last nine years, none in Paterson for six years, none in Reading for five years, none in Elizabeth and Syracuse for three years and none in Erie, Jersey City and Newark for two years. Utica reports a single death from diphtheria for fourteen years. New York records 12 deaths for 1947, all among residents. There were 18 deaths in 1946, 15 among residents (15 in 1945, 9 among residents, and 6 in 1944, all among residents). Philadelphia records 7 deaths (6 in 1946 and 3 in 1945), all among residents. Pittsburgh, although on the honor roll in 1944 with no death, has failed to return to this position. In 1947 there were 2 deaths, 1 among nonresidents. In 1946 there were 5 deaths, 3 among nonresidents. Buffalo reports 5 deaths, 3 among residents. In 1946 there were 16 deaths, 15 among residents (in 1945, 3 deaths, and in 1944, 1 death). After a period of five years without a death from either typhoid or diphtheria, Albany records 1 death from diphtheria among nonresidents in 1947. After a period of three years without a death from either cause, Trenton, N. J., reports 3 deaths from diphtheria among residents in 1947. Camden, N. J., reports 2 deaths from diphtheria for 1947, 1 among nonresidents. It should be noted that the Pennsylvania Department of Health has not made tabulations for nonresidents for Reading and Scranton and these data are unobtainable from the local health officers.

* Special census for 1941 gives rate of 0.4 for 1946 and 0.5 for 1941-1945 for Norfolk, and rate of 0.2 for 1945§ for Washington.
† *One third or more of the reported deaths from diphtheria were stated to be in nonresidents.*
‡ Incomplete data.
§ All deaths from diphtheria were stated to be in nonresidents.
‖ Special census for 1946 gives rate of 0.5 for 1946 for Washington.
¶ Special census for 1943 gives rate of 2.7 for 1945 and 2.9† for 1946 and 0.6 for 1947 and 1.1 for 1941-1945 for Baltimore and 0.9§ for 1947 for Richmond.

In 1940 Charlotte was added to the nine cities previously included in the South Atlantic states (table 3) (population 2,727,985). The figures for this city have been omitted in the tables for group comparison. The number of deaths in the original cities decreased to a new low of 15 deaths, the previous low being 17 in 1942. There were 46 deaths in 1946 and 39 in 1945. The rate has decreased from 1.68 in 1946 to 0.55 in 1947. The new rate is slightly lower than that of the New England cities (0.58). However, the South Atlantic group, in spite of the noteworthy improvement, is in fourth place. The number of deaths among residents has decreased from 32 in 1946 to 6 in 1947 (5 of these were in Baltimore and 1 in Jacksonville, Fla.). The number of deaths among nonresidents (9) exceeded those among residents (6). Four cities (there was only one in 1946) appear on the honor list (table 11), with no death from diphtheria (Miami, Norfolk and Tampa, Fla., and Wilmington, Del.). It is stated that the 3 deaths in Atlanta, 4 in Charlotte, 2 in Richmond and 1 in Washington, D.C., all occurred among nonresidents. Charlotte and Richmond have been without a death among residents for five years. Norfolk, Tampa and Wilmington record no death from either typhoid or diphtheria during the past two years. Baltimore reports a decrease in deaths from diphtheria. In 1947 there occurred 6 deaths (5 among residents), and in 1946 there were reported 27 deaths (19 among

* Incomplete data
† One third or more of the reported deaths from diphtheria were stated to be in nonresidents.
‡ All deaths from diphtheria were stated to be in nonresidents.

residents). The low point for Baltimore occurred in 1942, when there were only 2 deaths. Jacksonville records 3 deaths, 2 among nonresidents.

In obtaining data for the cities of the East North Central group (table 4), Gary, Ind., has been included since 1940. The figures for this city have been omitted in the tables for group comparison. The cities of this group (population 9,386,378) report only half as many deaths as in 1946 (28 in 1947 and 56 in 1946). The number of deaths among residents decreased from 42 in 1946 to 20 in 1947. The rate decreased from 0.60 in 1946 to 0.30 in 1947. This group of cities is again in second place. Together with the cities of the Middle Atlantic group, the West North Central group, the South Atlantic group and the New England group, there are now five groups (two in 1946) with a rate below 1.0 in 1947. Only six cities, however, report no death from diphtheria (Flint, Mich., Grand Rapids, Mich., Peoria, Ill., South Bend, Ind., Toledo, Ohio, and Youngstown, Ohio). There were also six cities on the honor roll in 1946, nine in 1945 and ten in 1942. It is stated that the 1 death in Milwaukee was among nonresidents. Grand Rapids reports no death for ten years, Peoria none for six years and South Bend none for three years. Canton, after a period of eight years with no death from diphtheria and a period of seven years with no death from either typhoid or diphtheria, records 1 death from diphtheria among residents in 1947. Gary, after a period of five years with no death from typhoid or diphtheria, reports 2 deaths from diphtheria, one among residents, in 1947. Youngstown records no death from typhoid and only 2 deaths from diphtheria (both in 1946) during the past six years. For ten years Fort Wayne has reported no death from typhoid and only 3 from diphtheria (1 in 1947, a girl aged 25). For ten years South Bend has reported only 1 death from typhoid (1 among nonresidents in 1944) and only 2 from diphtheria. Chicago records a decrease from 13 deaths in 1946 to 3 in 1947, all among residents (in 1945 there were 3 deaths and in 1943 there were 53). Detroit reports an increase in deaths from diphtheria from 4 (2 among residents) in 1946 to 7 (3 among residents) in 1947. Cincinnati records 3 deaths, 2 among residents; Cleveland reports 1 death among residents. The number of deaths in Columbus, Ohio, has decreased from 6 in 1946 to 3 in 1947 (2 among residents). Deaths in Indianapolis have decreased from 8 in 1946 (4 among residents) to 4 in 1947 (3 among residents). Akron and Dayton, Ohio, each report 1 death among residents.

¶ Deaths from diphtheria from Chapin's Municipal Sanitation.
# Special census for 1945 gives rate of 1.4§ for 1945 and 1.8 for 1946 and 0.7 for 1947 and 1.0 for 1941-1945 for San Francisco.

The cities in the East South Central states (table 5) (population 1,286,747) report an increase in deaths from diphtheria, but only among residents. In 1947, in this group of cities there were 17 deaths, with 8 among nonresidents (in 1946 there occurred 13 deaths, 9 among nonresidents; in 1945 there were 41 deaths, 25 among nonresidents). In 1943 this group reported a low of 8 deaths, only 2 of which were among residents.

The group rate increased from 1.01 in 1946 to 1.31 in 1947 (it was 3.18 in 1945; the low was 0.62 in 1943). In 1947 these cities are in seventh place (they were in third place in 1946 and in eighth place in 1945). One city (Knoxville, Tenn.) appears on the honor roll (table 11) with no death from diphtheria. This city also reports no death from typhoid in 1947 (table 12). It is stated that the 2 deaths in Nashville, Tenn., occurred among nonresidents. Following a period of two years with no death among residents, Memphis reports 7 deaths (2 among residents) in 1947. It should be emphasized that 5 of the 7 deaths in Memphis, Tenn., were among nonresidents. Chattanooga, Tenn., and Louisville, Ky., each record 3 deaths among residents. It is stated that of the 2 deaths in Birmingham, Ala., 1 was among nonresidents. The health officer of Chattanooga states that deaths among nonresidents are not tabulated and data from the Tennessee Department of Public Health is not yet available.

† Number of years for which there were no deaths from typhoid or diphtheria.

The nine cities in the West North Central states (table 6) (population 2,716,484) show a decrease in the diphtheria death rate (0.41 in 1947, 1.29 in 1946, 0.66 in 1945). The number of deaths has decreased from 35 (28 among residents) in 1946 to 11 (8 among residents) in 1947 (there were 18 in 1945, 10 among residents). The low point occurred in 1941, with a rate of 0.18 and 5 deaths (4 among residents). Only two cities (Des Moines, Iowa, and Wichita, Kan.) are on the 1947 honor roll (there were two in 1946, four in 1945). Wichita records no death from typhoid or diphtheria for five years. Des Moines reports no death from diphtheria for four years. It is stated that the 1 death from diphtheria each in Kansas City, Mo., and Omaha, occurred among nonresidents. St. Louis reports 3 deaths, all among residents (there were 4 such deaths in 1946 and none in 1945). Minneapolis records 2 deaths, 1 among residents (in 1946 there were 9 deaths, 7 among residents; in 1945 there were 3 deaths, all among residents, and in 1942 no deaths were recorded). St. Paul reports 2 deaths among residents (3 in 1946 and none in 1945); Duluth reports 1 among residents (7 in 1946, 4 among residents, but 2 deaths in the preceding ten years). The 1 death in 1947 in Kansas City, Kan., occurred among residents.

* Charlotte, Gary and Sacramento omitted.

The eight cities of the West South Central states (table 7) (population 2,048,692) report 21 deaths, 11 among residents (there were 27 in 1946, 18 among residents, and 51 deaths in 1945, 33 among residents). This constitutes the lowest number of deaths for this group of cities. The group rate decreased from 2.48 in 1945 to 1.32 in 1946 to 1.02 in 1947. The group as a whole ranks in sixth place, the rates being higher in the Mountain and Pacific group (1.45) and the East South Central group (1.31). Four cities (El Paso, Texas, Fort Worth, Texas, Oklahoma City and Tulsa, Okla.) appear on the honor roll. El Paso, Oklahoma City and Tulsa report no death from typhoid or diphtheria in 1947, and Fort Worth reports none among residents. In three cities (Dallas, Texas, Houston, Texas, and New Orleans) it is stated that one third or more of the deaths from diphtheria occurred among nonresidents (1 of 2 in Dallas, 4 of 6 in Houston and 4 of 6 in New Orleans). Of 12 deaths in New Orleans in 1946, 7 occurred among nonresidents. One city (there were two in 1946 and four in 1945) reports a rate in excess of 2.0 (San Antonio, Texas). In 1947 San Antonio records 7 deaths, 6 among residents (the same as in 1946).

* Five cities (Jacksonville, Miami, Oklahoma City, South Bend and Utica) are omitted from this summary because data for the full period are not available.

† Data for Fort Worth lacking.

‡ Census figures for 1940 used.

In 1940 Sacramento was added to the eleven cities included in the Mountain and Pacific group (table 8). The figures for this city have been omitted in the tables for group comparison. The original cities (population 4,186,039) report a decrease in the number of deaths from diphtheria (61 in 1947 and 71 in 1946). This is larger than the number of deaths (39) in 1941. The rate has decreased from 1.70 in 1946 to 1.45 in 1947. The group rate exceeds all other group rates for 1947 (table 16). Of the 61 deaths in 1947, 46 were among residents (52 among 71 in 1946). Three cities (Long Beach, Calif., Sacramento, Calif., and Tacoma, Wash.), with no death from diphtheria in 1947, are on the honor roll (table 11). Long Beach is the only city in this group that records no death from typhoid and diphtheria during the last two years (table 12). Sacramento and Tacoma report no death from either cause in 1947. It is stated that the 1 death from diphtheria in Spokane was among nonresidents. Two other cities (Portland, Ore., and Salt Lake City) record one-third or more deaths among nonresidents (1 of 2 in Portland and 4 of 7 in Salt Lake City). Three cities (Denver, Los Angeles and Salt Lake City) report rates in excess of 2.0. Adjusted to a 1945 census, the San Francisco rate is 0.7 (6 deaths). Adjusted to a 1946 census, the rate for San Diego, Calif., is 0.5 (2 deaths), the Los Angeles rate is 1.8 (32 deaths, 23 among residents), the rate for Oakland, Calif., is 0.2 (1 death). Adjusted to a 1944 special census, the rate for Denver is 2.1 (7 deaths) and that for Portland is 0.5 (2 deaths, 1 among residents).

Of the entire ninety-three cities there was none (three in 1946) with a rate in excess of 5.0 (table 14). This record has attained only in 1940. The number of cities with no deaths from diphtheria has increased from thirty in 1946 to thirty-nine in 1947. The largest number (forty) of cities found in this group was in 1940. For the eighty-eight cities (table 15) for which data are available since 1923, there occurred 197 deaths from diphtheria in 1947 (a new all-time low), 132 fewer deaths than in 1946. The previous low was 209 deaths in 1941. The rate for this group of cities remains for the ninth consecutive year less than 1.0. A new all-time low rate of 0.53 has been established. The rate for the ninety-three cities (0.53) is the same as that for the eighty-eight cities. The actual number of deaths (200) has decreased by 13 over the low of 1941. The decrease over a period of years has been impressive in all groups of cities. In comparing 1947 with 1946 the significant decreases have occurred in the New England, South Atlantic, East North Central and West North Central cities. Only the East South Central cities showed an increase. Diphtheria, like typhoid,

Table 16.—*Total Diphtheria Death Rates per Hundred Thousand of Population for Ninety-Three Cities According to Geographic Divisions*

	Population*	Deaths from Diphtheria		Diphtheria Death Rates				
		1947	1946	1947	1946	1941-1945	1935-1939	1930-1934
New England	2,579,152	15	36	0.58	1.40†	0.39	0.85	3.38
Middle Atlantic	13,129,185	32	50	0.24	0.38	0.19	0.65	2.50

* Census figures for 1940 used.

† One third or more of the reported deaths from diphtheria were stated to be in nonresidents.

continues to approach the vanishing point. Health officials continue to encourage protective treatments for infants and preschool children and recommend booster doses at time of school admission and later in life when conditions indicate that it is desirable. Diphtheria can be eliminated through health education and parental understanding by extending programs for the protection of susceptible groups.

Clinical Notes, Suggestions and New Instruments

TREATMENT OF ABSCESSES WITH ASPIRATION AND PENICILLIN

HARRY J. COHEN, M.D.
New York

Incision and drainage is an accepted and fundamental surgical principle in the treatment of abscesses and of purulent collections in the body cavities. The introduction of penicillin has modified this, so that at present drainage of the purulent material by aspiration and replacement with penicillin in isotonic sodium chloride solution has cured the condition in many instances and obviated the need for surgical intervention.

The procedure was first employed in this series at Harlem Hospital, August 1944, in the treatment of a newborn infant in whom numerous discreet nodular infections developed secondary to an infected scalp wound. Although sulfonamide drugs were administered orally for eleven days, the infant's temperature remained elevated, up to 102 F., and new nodules continued to appear. There were many nodules, and they were distributed on the entire back, buttocks, abdomen, thighs and legs. Blood cultures were negative on two occasions. As there was no response to the treatment with sulfonamide drugs, this was discontinued and penicillin therapy was started. The dose was 10,000 units given intramuscularly every three hours. The temperature returned to normal in two days, and the child's condition was much improved. Many of the hardened nodules were absorbed, while others became much larger and fluctuant, typical of subcutaneous abscesses. The surgical service in consultation advised incision and drainage of these abscesses. Since there were so many of them and since they were so widely distributed on the entire body, especially the back, buttocks and thighs, the problem of dressings and nursing care would have been extremely difficult. The conservative treatment of aspiration and replacement with penicillin was therefore deemed advisable. The abscesses were aspirated by means of a large bore needle attached to a syringe, and the purulent material was replaced with a solution of penicillin. Usually one aspiration and treatment with penicillin per abscess cavity was sufficient to cause absorption and healing of the abscess. At the outset the aspirated material showed Staphylococcus albus on culture; later, material of many aspirations was sterile. The temperature remained normal for about one week, and the intramuscular administration of penicillin was discontinued. [illegible] the child [illegible] no scarring of the body.

The procedure as practiced in the preceding instance and in the other cases in this series is described.

TECHNIC

Penicillin is administered for a few days until the infection has become localized. It may be given either orally, intramuscularly in oil and wax or, preferably, intramuscularly in solution every three hours. When fluctuation is evident and the abscess is soft, aspiration is performed by means of a 20 cc. Luer syringe attached to a 1½ inch (3.8 cm.) 18 gage needle. The needle is inserted into the most fluctuant area, and as much of the pus is aspirated as is possible. With the needle in situ, the syringe is detached and another syringe, containing 25,000 units penicillin per cubic centimeter of solution, is then attached to the needle in situ in the abscess cavity. The penicillin is injected into the cavity, causing it to be distended and become cystic again. The needle is removed, and firm pressure is applied for about a minute, to prevent leakage of the penicillin solution from the puncture wound made by the needle. Varying amounts of pus have been removed, in the average abscess about 3 to 5 cc., and this has been replaced by about an equal amount of penicillin solution. From experience, it seems preferable to wait until the abscess is rather soft, even though it may seem ready to open spontaneously; this method has yielded excellent results. The cystic swellin [illegible] to rep[illegible] this is unnecessary, as usually one treatment is sufficient and after about a week the mass is gradually absorbed.

COMMENT

The principle of this treatment is the same as in the direct instillations of penicillin into infected cavities after aspiration as practiced by others. It has been used in infected pleural and peritoneal cavities, bursae, bartholinian abscesses,[1] suppura- [illegible] in the closed treatment of acute [illegible]

The advantages of the treatment are numerous, and it is a valuable addition to the pediatrician's armamentarium. It can be performed in the office or home. Neither local nor general anesthesia is required, as the procedure is not painful. The method is especially useful in children, because it has elim[illegible] to [illegible] thighs and buttocks, exposed to the excreta, and with the older technic it was impossible to keep wounds clean, prevent contamination and secondary abscesses. It has greatly facilitated nursing care, and the children are not subjected to repeated painful dressings. In infections about the face and neck, where the prevention of scar formation is desirable, the cosmetic results have been gratifying. This was seen in two severe infections on the face and in several instances of cervical adenitis, in which no evidences of the previous infection remained after cure. No disadvantages have been encountered except for an occasional urticarial reaction due to sensitivity to penicillin.

Fifteen children suffering from abscesses of various parts of the body were treated by the method outlined. The results were uniformly successful; all were cured, and none of the abscesses required subsequent incision and drainage. The youngest patient was a premature infant, aged 3 weeks, who had a large abscess of one of the buttocks. Two children had multiple abscesses, and they were treated in the same manner. Six of the children suffered from acute cervical adenitis and then presented suppuration. The causative organisms were Staph. albus, Staphylococcus aureus, Streptococcus hemolyti- [illegible] er possible there was [illegible] r sulfadiazine or penicillin. Two patients were encountered that presented themselves too late for preliminary treatment, as the abscesses were ready for drainage. This was performed, and the penicillin instilled into the abscess cavities. The local condition became completely resolved. It is preferable to institute both predrainage and postdrainage systemic treatment, the latter being continued until the temperature is normal for about three days and the local condition shows evidence of the resolution of the abscesses.

SUMMARY

Abscesses of various parts of the body were treated by aspiration of the purulent material, and this was replaced with a solution of penicillin in isotonic sodium chloride solution. Fifteen patients were treated, with excellent results.

975 Walton Avenue.

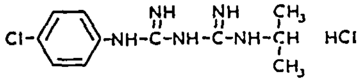
NEW AND NONOFFICIAL REMEDIES

The following additional articles have been accepted as conforming to the rules of the Council on Pharmacy and Chemistry of the American Medical Association for Admission to New and Nonofficial Remedies. A copy of the rules on which the Council bases its action will be sent on application.

Austin Smith, M.D., *Secretary.*

CHLORGUANIDE HYDROCHLORIDE. Guanatol-Lilly.--N^1-(*p*-chlorophenyl)- N^5-isopropylbiguanide hydrochloride.--$C_{11}H_{16}N_5Cl.HCl$.--M. W. 290.2. The structural formula of chlorguanide hydrochloride may be represented as follows:



Actions and Uses.- Chlorguanide hydrochloride is useful for the prophylaxis, suppression and treatment of malignant tertian (Plasmodium falciparum) malaria and for the suppression and treatment of benign tertian (Plasmodium vivax) malaria with the strains so far studied. The drug is only partly effective in preventing attacks of vivax malaria, since erythrocytic forms appear in the blood a short time after the drug is withdrawn. Other antimalarial drugs such as chloroquine or quinacrine are said to be preferred in the treatment of vivax malaria. Chlorguanide hydrochloride is the drug of choice for the treatment of falciparum malaria.

Chlorguanide hydrochloride disappears from the plasma in about 48 hours after the administration of a single dose of 0.5 Gm. About one half to one third of the drug is excreted by the kidneys. The drug does not accumulate in the body when given in therapeutic doses.

Toxic symptoms are not observed in the usual dosage regimen, but doses of 1 Gm. or more may produce vomiting, abdominal pain and diarrhea. Excessive doses may produce transient hematuria, epithelial cells and casts in the urine. Intramuscular injection of chlorguanide hydrochloride may result in local myonecrosis and inflammatory reactions. High doses may also produce a temporary myelocytic reaction in the blood.

As with other antimalarial agents, the response of various strains of plasmodia to the drug is variable, so that the average dosage schedule which is indicated may be subject to modification in accordance with the response of the strain involved.

Dosage.-A single dose of 0.3 Gm. weekly in the suppression of falciparum and vivax malaria. For the prophylaxis of falciparum malaria, 0.1 Gm. twice a week may be given; this dose is only partially effective against vivax malaria.

A dose of 0.1 Gm. three times daily, or 0.3 Gm. daily, for ten days is usually effective in producing a cure of falciparum malaria. The same dose is usually only partially effective against vivax malaria.

Tests and Standards.-Chlorguanide hydrochloride occurs as odorless, colorless, fine crystals or as a crystalline powder possessing a bitter taste. It is soluble in alcohol, slightly soluble in water and practically insoluble in chloroform and in ether. The pH of a filtered saturated solution is between 5.8 and 6.3. Chlorguanide hydrochloride melts between 248 and 252 C. It exhibits an ultraviolet absorption maximum at 2590 Angstroms when dissolved in ethyl alcohol ($E^{1\%}_{1cm.} = 690 \pm 7$).

Prepare 50 cc. of a saturated solution of chlorguanide hydrochloride in water and divide into five portions in separate test tubes. To one portion add 1 cc. of diluted nitric acid and 1 cc. of silver nitrate T.S.: a white precipitate forms. To another portion add 5 drops of iodine T.S.: an orange-brown precipitate forms. To another portion add 5 drops of potassium ferrocyanide T.S., rendered slightly acid to litmus with diluted nitric acid: a white precipitate forms which is soluble on addition of a few drops of diluted nitric acid. To another portion add 5 drops of a slightly acid solution of potassium dichromate T.S.: a yellow precipitate forms which is soluble in a few drops of diluted nitric acid. To another portion add bromine T.S., dropwise: a yellow precipitate forms which immediately redissolves on mixing; on addition of an excess of bromine T.S. a permanent orange precipitate forms.

Dissolve about 100 mg. of chlorguanide hydrochloride in 25 cc. of water in a separatory funnel and add 10 cc. of tenth normal sodium hydroxide. Extract the precipitated chlorguanide base with 25 cc. of ether. Separate, filter the ether extract, evaporate to near dryness, and dry the residue at 100 C.: the residue melts between 130 and 135 C.

Dry about 1 Gm. of chlorguanide hydrochloride, accurately weighed, at 100 C. for 3 hours: the loss in weight is not more than 0.3 per cent. Ash about 0.5 Gm. of chlorguanide hydrochloride, accurately weighed, in the presence of sulfuric acid: the residue is not more than 0.1 per cent.

Transfer about 0.2 Gm. of chlorguanide hydrochloride to an Erlenmeyer flask; add 50 cc. of water and dissolve the solid. Add 1 cc. of nitric acid and exactly 40 cc. of fiftieth-normal silver nitrate. Add 3-5 cc. of nitrobenzene and swirl the flask to entrap the precipitated silver chloride. Add 3 cc. of ferric ammonium sulfate T.S., and titrate with fiftieth-normal ammonium thiocyanate. Each cc. of fiftieth-normal silver nitrate is equivalent to 0.709 mg. of chlorine. The readily ionizable chlorine content is not less than 11.5 per cent nor more than 12.3 per cent, calculated to the dry substance.

Determine the nitrogen content of chlorguanide hydrochloride by the Kjeldahl method: the nitrogen content is not less than 23.5 per cent nor more than 24.5 per cent, calculated to the dry substance.

Transfer about 0.2 Gm. of chlorguanide hydrochloride to a separatory funnel, add 25 cc. of water and 10 cc. of sodium hydroxide T.S. Extract the precipitated chlorguanide base with successive 30 cc., 25 cc., 10 cc., 10 cc. and 10 cc. portions of ether. Combine the ether extracts, wash with 10 cc. of water and filter the ether solution through a cotton pledget. Evaporate the combined ether extracts in a tared beaker using a stream of warm air. Dry the residue at 100 C. for 1 hour: the weight of the residue is not less than 85.7 per cent nor more than 89.2 per cent, calculated to the dry substance.

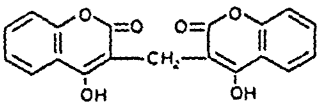
Tablets Guanatol Hydrochloride: 25 mg., 50 mg. and 100 mg.

DICUMAROL.—3,3'-methylenebis(4-hydroxcoumarin).—$C_{19}H_{12}O_6$.—M. W. 336.286. The structural formula of "dicumarol" may be represented as follows:



Actions and Uses.—"Dicumarol" causes a lengthening of the prothrombin time by decreasing the prothrombin concentration of the blood. Although the exact mode of action is not known, it is assumed that the drug acts on the liver to retard prothrombin production, since the circulating prothrombin present in blood is not affected in vitro by the addition of "dicumarol"; the effect of the drug requires 12 to 24 hours to develop and persists for from 24 to 72 hours after discontinuance of therapy.

"Dicumarol" may be used in the prophylaxis and treatment of intravascular clots. It may be used alone or as an adjunct to heparin in the treatment of postoperative thrombophlebitis and pulmonary embolism, acute embolic and thrombotic occlusion of peripheral arteries and recurrent idiopathic thrombophlebitis.

"Dicumarol" does not affect thrombi or emboli already present, nor does it increase the local blood supply of an area affected by an embolism. The drug can only be expected to retard further intravascular clotting and prevent propagation of the thrombus or embolus.

Since the ultimate outcome of acute coronary thrombosis is to a large extent dependent on extension of the clot and on the formation of mural thrombi in the cardiac chambers with subsequent embolization, "dicumarol" has been used as an adjunct in the treatment of this condition.

Dosage.—On the first day the prothrombin time is determined to insure that it is not abnormally high. One dose of 200 to 300 mg. is given, depending on the size and condition of the patient. On the second day the per cent prothrombin is determined, and a second dose of 100 to 200 mg. of the drug is given only if the prothrombin activity is more than 25 per cent. On successive days 100 to 200 mg. is administered if prothrombin activity is more than 25 per cent.

If prothrombin activity drops below 15 per cent, or if signs of bleeding appear, menadione sodium bisulfite 72 mg. is given intravenously slowly. This may be given along with transfusions of fresh whole blood.

Tests and Standards

"Dicumarol" occurs as a white or slightly buff-colored crystalline powder. It melts in the range 287-293 C. It is soluble in aqueous alkali and in pyridine, slightly soluble in benzene and in chloroform, and practically insoluble in water, alcohol and ether.

Dissolve 0.1 Gm. of "dicumarol" in 10 cc. of sodium hydroxide T.S. and allow the solution to stand: the solution gradually darkens and eventually becomes dark brown.

Dissolve 0.2 Gm. of "dicumarol" in 5 cc. of hot pyridine. Cool, and add 2 cc. of acetic anhydride. After crystallization is complete, filter, wash with ethanol and recrystallize from benzene. The product melts between 249-252 C. with decomposition.

Suspend 0.1 Gm. of "dicumarol" in 10 cc. of water, heat to boiling and filter while hot. Cool the filtrate and add 2 drops of silver ammonium nitrate T.S. to 5 cc. of the clear filtrate: no precipitate forms (*absence of formaldehyde and chlorides*).

Add 1 drop of ferric chloride T.S. to the remaining 5 cc. of filtrate: no color develops (*absence of salicylates and 4-hydroxycoumarin*).

Dry 0.5 Gm. of "dicumarol," accurately weighed, for 2 hours at 100 C.: the loss in weight does not exceed 0.5 per cent.

Dissolve 1 Gm. of "dicumarol" in enough sodium hydroxide T.S. to give complete solution, and dilute to 20 cc. with water. Add 5 drops of 10 per cent sodium sulfide solution: *no more turbidity develops than corresponds to 30 ppm. of lead* (*U.S.P. XIII*).

Ash about 0.2 Gm. of "dicumarol," accurately weighed: the amount of residue is negligible.

Transfer about 0.3 Gm. of "dicumarol," accurately weighed, to a 100 cc. beaker. Add 5 cc. of sodium hydroxide T.S. and then dilute with water to about 50 cc. Acidify with diluted hydrochloric acid, cool in an ice bath and filter while cold through a tared Gooch crucible. Wash with a small amount of ice water and dry at 100 C. to constant weight: the "dicumarol" content is not less than 97.5 per cent or more than 102.5 per cent.

DICUMAROL TABLETS:

Weigh 20 "dicumarol" tablets and grind them to a powder. Weigh accurately sufficient powder to give a *sample equivalent to about 50 mg. of "dicumarol."* Add 50 cc. of distilled water and 10 cc. of diluted ammonia solution to the sample stir and allow to stand 10 minutes with frequent stirring. Filter and wash the filter with water. Acidify with diluted hydrochloric acid, cool in an ice bath and filter onto a tared Gooch crucible wash with a few cc. of ice cold water. Dry to constant weight at 100 C: the "dicumarol" content is not less than 95 nor more than 105 per cent of the claimed amount.

Anaydin *(Powder)* : 25 Gm. and 100 Gm. bottles.

Pills Anayodin: 0.25 Gm., enteric coated with shellac and magnesium stearate.

U. S. Patent 232,215

Council on Physical Medicine

The Council on Physical Medicine has authorized publication of the following reports. HOWARD A. CARTER, *Secretary.*

DYSONIC HEARING AID, MODEL I, ACCEPTABLE

Distributor: Dynamic Hearing Aids, Inc., 43 Exchange Place, New York 5.

The Dysonic Hearing Aid can be used either with microphone, amplifier and batteries in a single case or with the batteries in a separate case. The case is of drawn aluminum. The upper section carries the microphone and amplifier. Two interchangeable lower sections are provided, one of which carries the power supply of the instrument when used as a single unit. It is replaceable by a light lower section containing connections for separate batteries. It can be used with either crystal or magnetic receivers and for either bone or air conduction.

Dimensions And Weight

Single Unit: 146 by 60 by 25 mm. (5 3/4 by 2 3/8 by 1 inch); 200 Gm. (7 ounces).

Two Piece Unit:

Microphone: 95 by 60 by 25 mm. (3 3/4 by 2 3/8 by 1 inch); 120 Gm. (4.2 ounces).

Batteries: Total weight 285 Gm. (10 oz.).

A Diameter 25 mm., length 95 mm.

B 76 by 64 by 24 mm. (3 by 2½ by 15/16 inch).

Battery Data for Single Unit

Type of Cell	Voltage	Current Drain (Milliamperes)
A Mercury	1.3	55.0
B Carbon-zinc	22.5	0.2
A Carbon-zinc	1.4	62.0
B Carbon-zinc	33.0	0.85

Acoustical Gain

Measurements were made with only a few of the many possible combinations of receivers, volume and control settings, and B battery voltages. Gains in decibels in the sound pressure level in a 2 cc. coupler over that on the face of the microphone for a few typical settings are tabulated below. The B battery was delivering 33 volts, the volume control was three-fourths full on, and the input level was 0.02 dyne per square centimeter. Seven frequencies were tried.

Frequency (Cycles Sec.):	256	512	1,024	1,200	2,048	3,100	4,096	
Crystal receiver								
Tone control 1 dot	30	38	48	55	40	48	45	db.
Tone control 2 dots	26	32	44	51	35	42	38	db.
Tone control 3 dots	26	32	42	49	29	31	26	db.
Magnetic receiver								
Tone control 1 dot	39	43	59	58	56	28	18	db

Spot checks with other combinations showed that the acoustical gain was sufficient to meet the requirements for acceptance.

Approximate values of the maximum pressure levels set up in the 2 cc. coupler with a 33 volt B battery and the magnetic receiver are shown as follows:

Frequency Cycles/Second	Input Level Decibels	Output Level Decibels
500	55	109
1,024	70	122
2,048	70	113

The usual syllable and articulation tests were made with a hard-of-hearing subject, using the single unit arrangement and the magnetic receiver:

Receiver Magnetic	Test Syllables	Test Sentences
Air conduction	94 per cent	100 per cent
Bone conduction	90 per cent	98 per cent

The whispered voice was heard and understood at a distance of 5 feet (152 cm.) by a hard-of hearing subject with an average hearing loss of 45 decibels in the speech range.

The Council on Physical Medicine voted to include the Dysonic Hearing Aid, Model I in its lists of accepted devices.

DICKSON PARAFFIN BATH WITH DRAIN MODELS BB, D2, DD AND E ACCEPTABLE

Manufacturer: Thermo Electric Company, 1012 West Superior Avenue, Cleveland 13.

The Dickson Paraffin Bath consists of a tub enclosed in insulating material which in turn is contained in an outside casing. The tub contains from 8 to 40 Kg. (18 to 90 pounds) of a mixture of paraffin and oil that can be melted and kept warm by an electric heating device. The heating elements are at the bottom of the tub and are covered with a special composition cement baked onto the tub. The elements consist of (A) a melting element of approximately 1,300 watts controlled by a time switch and a high limit control and (B) a maintenance element controlled wholly or in part by a close differential thermostat designed to hold the temperature of the paraffin to within 2 degrees C. of the set temperature.

The tub is mounted either on a stand or in a table. The four models differ in the size and shape of the tank as well as in the type of mounting. The differences are indicated in the accompanying table:

Comparison of Models of the Dickson Paraffin Bath

	Model BB		Model D2		Model DD	
Mounting	Stand		Four caster on base		Stand	
	Mm.	(In.)	Mm.	(In.)	Mm.	(In.)
Over-all height (of tank)	368	(14½)	559	(22)	343	(13½)
Over-all length (of tank)	787	(31)	559	(22)	457	(18)
Over-all width (of tank)	381	(15)	483	(19)	260	(10¼)
Wattage required by element	1,100 watts		1,300 watts		500 watts	
Controls for element	Time switch and high temp. control		Time switch and high temp. control		Toggle switch and high temp. control	
Drain	Optional		Optional		No drain	
Shipping weights	Kg.	(Lb.)	Kg.	(Lb.)	Kg.	(Lb.)
Paraffin bath*	45.3	(100)	59.0	(130)	19	(42)
Stand*	11.8	(26)	—	—	10	(22)
Paraffin*	29.0	(64)	45.3	(100)	In bath	

* Packed to ship.

Model E follows the same specifications as model BB except that the tank is mounted in a massage table. The drain, supplied optionally, is in one end of the bath. It consists of a shutoff cock, an outlet at the front end of the bath, and a special element with special wiring to a thumb switch that insures clearing the drain of solidified paraffin. The drain is a convenience in keeping the bath clear of the sediment and perspiration that settle to the bottom

The apparatus was investigated in a clinic acceptable to the Council and was found satisfactory. The Council on Physical Medicine voted to include the Dickson Paraffin Bath with Drain, Models BB, D2, D3 and E, in its list of accepted devices.

1947 MEARS AUROPHONE, MODEL 98, ACCEPTABLE

Manufacturer: Mears Radio Hearing Device Corp., 1 West Thirty-fourth Street, New York.

This hearing aid, also called the " New Patented Auropac, " is a vacuum-tube type of instrument, with A and B batteries contained in a separate zipper case of black leather. The microphone and amplifier case of moulded plastic is cylindrical in shape and carries a single rotary control for volume and on and off switch. The off position is not marked.

Two receivers were supplied with the instrument sent to the Council investigator for examination.

Dimensions and Weight.—Microphone and amplifier case: 76 mm. (3 inches) in diameter, with 13 mm. (½ inch) connector plug, 25 mm. (1 inch) thick; weight, 128 Gm. (4½ ounces).

Battery case with 22½ volt B battery: 67 by 64 by 25 mm. (2 5/8 by 2½ by 1 inch); weight 142 Gm. (5 ounces).

Battery case with 30 volt B battery: 64 by 76 by 29 mm. (2½ by 3 by 1 1/8 inches); weight 184 Gm. (6½ ounces).

Battery Data

	Voltage	Current	
A battery (zinc-carbon)	1.5 volts	64 to 66 milliamperes	
B battery (zinc-carbon)	22.5 volts	0.2 milliampere	(no sound)
		0.5 milliampere	(squealing)
	30.0 volts	0.5 milliampere	(no sound)
		0.9 milliampere	(squealing)

Acoustical Gain

Measurements of the gain in decibels in the sound pressure level set up in a 2 cc. coupler over the sound pressure level at the face of the microphone were made at nineteen frequencies between 200 cycles and 4,096 cycles for an input level of 50 decibels measured on the B scale of a General Radio sound level meter.

The following table states in decibels the acoustical gain measured for two different B batteries at each of seven different frequencies, when the volume-control was at three-fourths full:

Condition	256	512	1,024	1,200	2,048	3,100	4,096
30 volt B battery, large receiver	51	45	55	56	45	40	35 db.
22½ volt B battery, small receiver	44	35	48	49	35	30	23 db.
30 volt B battery, small receiver	45	39	47	56	47	34	24 db.

The Council on Physical Medicine voted to include the 1947 Mears Aurophone, Model 98, in its list of accepted devices.

MAICO MODEL R S GROUP PHONOGRAPHIC AUDIOMETER ACCEPTABLE

Manufacturer: The Maico Company, Inc., Maico Building, North Third Street, Minneapolis 1.

The Maico Model R S Group Phonographic Audiometer is designed for preliminary screening hearing tests, to meet the need for devices that will save the otologist the time and effort of administering individual tests to large groups in which the expected incidence of hearing defects is low. It is understood that a more complete audiometric test will thereafter be given to those who miss many of the test words.

The instrument consists of a synchronous self-starting motor, a crystal pick-up, an amplifier, a carrying case and one to four trays containing ten to forty magnetic earphones with head bands. It operates from a 115 volt, 60 cycle line and consumes 35 watts.

Each of the four trays of phones, which may be purchased with the instrument, is plugged into a separate output jack. These jacks are connected in such a way that if one tray of phones is disconnected, an equivalent load is placed across the jack terminals so that the output level in the other air receivers will not be affected.

The Model R S Phonograph is designed for use with the Maico Group Hearing Test Record of Fading Numbers, Serial numbers 2109-2110. The test words on these records in each of the eight columns vary in output level from 30 decibels above the threshold of hearing to 3 decibels below the threshold in steps of 3 decibels. Half of the columns are a woman's voice and the other half a man's voice. The calibration of the R S Phone was originally determined by hearing survey tests conducted in Maico's soundproof room on more than 30 persons with normal hearing. Test standards have been set up so that all Maico R S Phonographic Audiometers will have the same calibration within plus or minus 2 decibels when they leave the factory.

The specimen submitted by the firm was examined by a special investigator for the Council, who not only studied its construction but also compared the results it gave with those from two other audiometers in a trial in which 1,000 school children of various ages were used. One of the last-named audiometers was phonographic, the other was of the pure tone type.

The investigator reported that the Maico instrument was constructed sturdily and compactly, that the receivers were of high quality and that the cords, contacts and other accessories were able to stand rugged service He stated that the design showed careful planning to insure consistent performance. He found that any single receiver could be removed easily for repair without tying up a whole tray of receivers or affecting the output of the remaining phones. He noted that the special test recording of a 1,000 cycle tone makes it possible to carry out a quick, rough check of the receivers, and that there is a special variable set screw with which the proper calibration of the equipment can be maintained in the field using the special test record just referred to and a meter supplied by the manufacturer. He remarked that this model has the weakness of not selecting high frequency loss cases which is inherent in all equipment of the phonographic type, but at present this type of screening testing is recognized and in common use; the present model overcomes some conditions which in the past made this type of testing less satisfactory than it could have been.

The Council on Physical Medicine voted to include the Maico Model R S Group Phonographic Audiometer in its list of accepted devices.

EDITORIAL ANNOUNCEMENT

The compositors returned to work on Monday, June 28. This issue of The Journal has been prepared in part by the use of Vari-Typer machines.

THE PROBLEMS OF VAGOTOMY

Most of the older reports of vagotomy in animals, written before 1900, says Alvarez,[1] are of little value today because experimenters cut the vagi so high in the neck or the thorax that they destroyed fibers supplying the larynx, heart, lungs and esophagus. As a result, the animals promptly died. The work of later experimenters lacked roentgenographic studies or direct observation of the effect of vagotomy on the digestive tract. Pavlov and his co-workers demonstrated that vagotomy in dogs abolishes the cephalic phase of the gastric secretion produced by sham feeding. The French investigators Arthaud and Butte reported in 1889 that their vagotomized animals suffered from anorexia, vomiting, loss of weight and cutaneous lesions. Carlson found that bivagotomy in dogs produced a prolonged decrease in gastric tonus. According to Shay, Komarov and Gruenstein, vagotomy produced so much motor paresis in rats that the animals could be kept alive only on a liquid diet containing peptones instead of proteins. Hartzell in 1929 cut the vagi transthoracically in 6 dogs and subdiaphragmatically in 2. Three of the 6 survived for a study lasting five months. They all showed subacidity. Cutting one vagus nerve produced little effect either in animals or in man. Animal experimentation demonstrated that cutting of the vagi near the diaphragm did not as a rule affect the heart or respiration.

The concept that the hypersecretion in gastroduodenal ulceration is largely neurogenic suggested to Dragstedt the feasibility of treating patients with intractable gastroduodenal ulceration by an operation designed to remove as completely as possible the vagus innervation of the stomach. The most striking effect of this operation on the patient with chronic ulcer was the immediate and often dramatic relief of pain and distress on an unrestricted diet and without medicaments. Delayed gastric emptying and diarrhea have proved to be transitory. The transabdominal approach was later adopted by Dragstedt and most surgeons because it offered an opportunity to inspect the abdominal viscera. By pulling down the lower end of the esophagus, a more or less complete vagotomy could be done.

Since the report by Dragstedt and Owens in 1943, some 425 vagotomies were performed by these workers, altogether some 10,000 in the United States and about 2,000 abroad. The consensus is that vagotomy is a particularly valuable procedure in the treatment of peptic jejunal ulcer. If performed for a duodenal ulcer the operation is best combined with a gastroenterostomy. Gastric ulcer in the opinion of Lahey, Walters and other surgeons should be treated by partial gastric resection rather than by vagotomy. In the experience of Walters and his co-workers at the Mayo Clinic, vagotomy gave results that were "inconstant, variable and unpredictable." While there was relief of pain, the patients suffered much discomfort due to retention of gastric contents. Some of the patients complained of frequent belching, of foul-smelling gas, fulness and bloating after meals, and a few have complained of nausea and diarrhea. Subsequent operations have been necessary in some instances to remove a persistent ulcer or to provide drainage.

Some of the questions that have not as yet been answered by vagotomy are: 1. Will the vagi regenerate in the course of time? 2. Will vagotomy protect man against the production of ulcers? 3. Will vagotomy in which a gastroenterostomy was added as a part of the procedure prevent the formation of jejunal ulcer?

COOPERATION WITH NATIONAL CONGRESS OF PARENTS AND TEACHERS

The National Congress of Parents and Teachers recently asked the House of Delegates of the American Medical Association to request the state medical societies to appoint committees or arrange for representation in conferences in the several states between medical societies, dental societies, health departments, educational agencies and the National Congress of Parents and Teachers, looking toward the improvement of health services and health education for school children.

The communication[1] was received just prior to the Annual Session of the American Medical Association, considered by the Board of Trustees, and introduced into the House of Delegates too late for committee action. A resolution[2] was also introduced into the House of Delegates at one of its later meetings and will be acted on at the Interim Session of the American Medical Association in St. Louis in December 1948.

---

[1] Alvarez, W. C.: Sixty Years of Vagotomy, Gastroenterology **10**: 413-441 (March) 1948.

[1] Letter from National Congress of Parents and Teachers, June 1948.

[2] Proceedings of the Chicago Session, J. A. M. A. **137**: 963 (July 10) 1948.

The history of cooperation between the National Congress of Parents and Teachers and the American Medical Association is a long and continuous record of joint effort toward the objectives stated. Since 1925 Dr. W. W. Bauer, Director of the Bureau of Health Education of the American Medical Association, and his predecessor have been members of the National Advisory Committee on the Summer Roundup of Children and its successor, the Committee on Health and Summer Roundup, of the National Congress of Parents and Teachers. For many years the Roundup blanks were printed on the presses of the American Medical Association, and for some of those years half the annual order was donated to the Congress with the compliments of *Hygeia, The Health Magazine*. Cooperation has not halted at the national level, for in many states and numerous local areas medical and parent-teacher groups have cooperated in the examination of preschool children in the Summer Roundup and in providing the health needs which were disclosed by the examination.

Emphasis by the National Congress on the integrity and responsibility of the home has met with warm sympathy from the medical profession, as has insistence by the Congress on the recognition of local autonomy in the furtherance of health and social welfare projects.

When, as seems probable, the House of Delegates adopts the pending resolution, the action will serve as a confirmation and a renewed pledge of cooperation between two associations representing doctors and their patients. In the meantime, action under the established cooperative relationships will continue.

Current Comment

A BIBLIOGRAPHY OF GROUP MEDICAL PRACTICE

The Bureau of Medical Economic Research has recently made available a 41 page annotated bibliography of group medical practice covering 234 items published during the period 1927 to 1947. Each reference is summarized in a few sentences. The 234 items include 127 in medical society journals, 10 in hospital association journals, 2 in publications of governmental agencies and 95 in other publications, mostly in the medical field. The director of the Bureau, Frank G. Dickinson, Ph.D., notes in the preface that most of the references abstracted favor group practice. He writes: "Upon reflection the reader will realize that this would be the inevitable result of our attempts to scan all the literature, as the advocates of change are always more prolific in their writings. The distribution (of the 'pro's' and 'con's') is and must be sharply out of line with the current position of group practice, which claims only slightly more than 2 per cent of the physicians engaged in the active practice of medicine in the United States." This annotated bibliography is a progress report of the Bureau's study of group practice authorized by the House of Delegates at Atlantic City, N. J., June 1947; it is the fourth in a series of Bureau publications, the first and second of which were prepared under the direction of Dr. R. G. Leland in 1933 and 1940.

ALCOHOLICS ANONYMOUS

The increase in alcoholism in the United States constitutes a health problem. Modern medicine regards alcoholism as a sickness whose etiology is to be sought in the personality of the excessive drinker and in his social milieu. Apparently Alcoholics Anonymous is effective in a considerable proportion of cases because of psychologic implications inherent in the method. Ritchie[1] notes that the membership, starting from 100 in 1939, has grown to more than 40,000. Alcoholics Anonymous is a program of rehabilitation created and administered by the alcoholic addicts themselves. The organization is open to everybody without regard to economic status, sex, religion or color (the last with some reservations). The groups are supported by voluntary contributions of their own members. Public solicitation of funds is rejected as dangerous; acceptance of large gifts from any source is considered unwise. The principle of anonymity has an invaluable spiritual significance. The *A. A. Grapevine*, which is the national organ of the Alcoholics Anonymous, serves as a medium of expression and as an instrument for the diffusion of the principles on which the fellowship operates. The basic principle which the alcoholic addict must accept on joining Alcoholics Anonymous is the total abstinence from alcoholic beverages. The attitude of Alcoholics Anonymous toward the alcoholic addict is thoroughly modern so far as it considers alcoholism a sickness and the alcoholic addict a sick man. By accepting the view that he is sick, that his drinking is the manifestation of a deep-seated compulsion, the alcoholic addict is relieved of moral responsibility for his past drinking behavior. The informal group meetings place the alcoholic addict in a social situation in which he has status and prestige; he is accepted as a full-fledged member of an ingroup. The novice is encouraged to strive for but twenty-four hours' sobriety, which of course is a much less formidable and less terrifying prospect than abstinence for life. The acceptance of a "Power greater than ourselves" is considered by the great majority of members as the core of the movement. Ritchie believes that the therapeutic effectiveness of Alcoholics Anonymous comes from its use of a spiritual force to attack the narcissism of the alcoholic addict. This aspect of the movement, many members insist, is to be regarded not as religious but as spiritual. According to the reports emanating from the central office of Alcoholics Anonymous 75 per cent of those who "really try" obtain a cure. This is a high rate of recovery judged by any standard.

ORGANIZATION SECTION

Official Note

PUBLIC RELATIONS NEWSLETTER

The Public Relations Department at American Medical Association Headquarters has developed a new public relations newsletter and exchange which will be sent to all state medical societies from time to time as material accumulates. The public relations newsletter will select the best of what each state medical society is doing in public relations and distribute these ideas to other state societies. Ideas and materials developed in American Medical Association headquarters also will be included in the exchange, the second half of which will be entitled "The PR Doctor" and contain comment describing the exchange material. The complete package constitutes a convenient filing and reference unit for public relation ideas and programs. The presidents, secretaries, journal editors and chairmen of public relation committees of state societies will receive the "PR Doctor" newsletter without the exchange items, as will the trustees, officers and members of the house of delegates of the American Medical Association. The newsletter is expected to be useful to state and county medical societies in delineating trends, activities and current opinion on medical public relation topics.

Washington Letter

(From a Special Correspondent)

Aug. 18, 1948.

Plans for Implementing National Health Assembly

A special steering committee for the National Health Assembly held its first meeting July 28. Without a single dissent, according to Oscar R. Ewing, Federal Security Administrator, the group recommended that it continue to function—on a permanent voluntary basis—as a vehicle for carrying out proposals made by the National Health Assembly held here last May. Cornelius Wood was designated to continue as executive secretary, a position he had filled since the resignation recently of Howard Kline. The committee also authorized negotiations with publishers for printing an edited transcript of the proceedings of the May conference, which was called by Ewing. Other objectives, as agreed at the July 28 meeting, will be to encourage and help local communities to assess their health needs; to stimulate the inception of regional, state and local health conferences with broad representation of lay and professional groups, and to cooperate with public and private organizations. In attendance at the meeting were all members of the steering committee, appointed by Mr. Ewing, except Nelson Cruikshank, American Federation of Labor, who was out of the country. They were: Graham L. Davis, American Hospital Association; Miss Katherine Densford, American Nurses' Association; Dr. Vlado A. Getting, Massachusetts Commissioner of Health; Mrs. Mary Lasker, New York; Dr. George F. Lull, American Medical Association; Mrs. Eugene Meyer, Washington, and Jerry Voorhis, Cooperative League of U. S. A.

Food and Drug Administration Cites Siliform Ampuls and Congo Red Solution

During the week, the Food and Drug Administration urged return of all outstanding stocks of "siliform ampuls" and, in a separate action, cautioned manufacturers of congo red solution that a dye used in its manufacture contains a free color acid which is under suspicion following two deaths and numerous adverse reactions after intravenous administration of the solution. Druggists and physicians were advised to return all supplies of "siliform ampuls" to the manufacturer, Heilkraft Medical Co., Dorchester, Mass., because examination of samples collected on the market revealed that the injection material is not sterile. Preceding the analysis of market samples, a routine examination of the Heilkraft factory disclosed that "siliform ampuls" were being processed without sterilization. Roundup of the product is expected to be difficult, since many of the sales by wholesalers cannot be traced and distribution covers thirty-seven states from Maine to California. Some stocks dating to 1946 have been found on the market. The congo red warning by Food and Drug Administration followed a notification received from one manufacturer that 2 deaths and a number of alarming reactions were recently observed after use of the solution. "While our investigations are still incomplete," said the federal agency, "it appears from the information developed thus far that it is imperative that manufacturers of congo red solutions for injection take every precaution to insure that the free color acid is not present in the ampuled material."

Appoints Medical Advisory Committee

Scheduled to hold its first meeting in August, the Medical Advisory Committee appointed by Chairman Arthur M. Hill of National Security Resources Board consists of the following: Drs. William P. Shepard, San Francisco; A. C. Bachmeyer, Chicago; James C. Sargent, Milwaukee; Edward L. Bortz, Philadelphia; Michael E. DeBakey, New Orleans, and Percy T. Phillips, New York. The group will work in close cooperation with Dr. James A. Crabtree, director of the board's Medical Services Division, which has broad responsibilities in mobilization and maximum utilization of the nation's medical, public health and hospital resources.

Swigart Joins National Blood Program

Appointment of Richard P. Swigart as assistant to the administrator of the National Blood Program has been announced by the American Red Cross. Affiliated with the Red Cross since 1936, Mr. Swigart for the past year has been deputy manager of the North Atlantic Area, with headquarters in New York City. He is a native of Chicago and attended Knox College and the University of Chicago. Recruitment of donors will be one of his responsibilities, under direction of Dr. Ross T. McIntire, director of the National Blood Program.

Study of Eye-Protective Glasses

National Bureau of Standards will soon publish, as Circular C-471, a comprehensive report by Ralph Stair entitled "Spectral Transmissive Properties and Uses of Eye-Protective Glasses" and based on investigations by the author of some 200 glasses intended for antiglare use or for industrial operations where injurious amounts of ultraviolet, luminous or infra-red radiant energy are present.

Senators Debate Health Insurance

Senators Kem (Republican, Missouri) and Murray (Democrat, Montana) were principals in a lively debate in the Senate August 3, the issue revolving about California Governor Warren's espousal of the health insurance principle. Senator Kern delivered a speech stating that he is opposed to "socialized medicine," which he characterized as "a distinct threat to the medical and allied professions as we now know them and to our American way of life." Senator Murray, co-sponsor of the Murray-Wagner-Dingell bill for compulsory national health insurance, reminded Senator Kem that Governor Dewey's Republican running mate, Governor Warren, is a champion of health insurance. The rejoinder was that the Californian has confined his efforts to establishment of state—not national—health insurance, which is "an entirely different thing from establishing a comprehensive, compulsory federal system." The debate is reported on pages 9843 to 9848 of the *Congressional Record* for August 3. The *Congressional Record* for August 4 (pages A-5087 to 5092) contains a speech by Rep. Forest A. Harness (Republican, Indiana) reviewing charges which he has made in the past on numerous occasions against alleged federal propaganda in behalf of compulsory health insurance.

New Members of Mental Health Council Appointed

Newest appointees to the National Advisory Mental Health Council are Drs. Leo H. Bartemeier, associate professor of psychiatry at Wayne University College of Medicine, and Carlyle Jacobsen, dean of the Graduate School, State University of Iowa. The former succeeds Dr. David Levy, of Columbia University, and Dr. Jacobsen takes the seat formerly held by Dr. Edward A. Strecker, University of Pennsylvania.

GOVERNMENT SERVICES

ARMY

COMMITTEE TO STUDY MEDICAL INDEXES

The Surgeon General on July 7 set up a committee of consultants for the study of the indexes to medical literature published by the Army Medical Library. The first meeting of the committee will be held in September. The members are: Drs. Lewis H. Weed, chairman; John F. Fulton, Sanford V. Larkey, Chauncey D. Leake, William S. Middleton, Ebbe C. Hoff, Eugene E. Scott, Mortimer Taube, Morris Fishbein, ex officio, and Colonel J. H. McNinch, ex officio, Mr. Ralph R. Shaw and Miss Janet Doe.

MEETING OF LIBRARY CONSULTANTS

The annual meeting of the Association of Honorary Consultants to the Army Medical Library will be held at the Statler Hotel, Washington, D. C., October 22. The formal meeting of the association will be for one day instead of the customary two. The meetings of the standing committees will be held either the day before or the day following the formal meeting, at the discretion of the chairmen. The spring meeting of the executive committee was held in Philadelphia May 28, with Dr. Chauncey D. Leake, of the University of Texas School of Medicine, presiding.

Dr. Robert L. Swain, chairman, Board of Trustees, United States Pharmacopoeial Convention, has been appointed an Honorary Consultant to the Library by the Surgeon General.

WOMEN'S MEDICAL SPECIALIST CORPS

The 80th Congress authorized the establishment of a Women's Specialist Corps in the Regular Army and a section in the Officers' Reserve Corps. This enactment, signed by the President April 16, 1947, made dietitians, physical therapists and occupational therapists a permanent part of the Regular Army. The policy of the Department of the Army is to procure and train an adequate number of officers in this branch of the service. These officers receive the same pay and allowances as other Regular Army officers of the same rank. The base pay for a second lieutenant is $180 a month plus $60 for rental for those with dependents and $45 for those without dependents, together with an allowance of $42 for subsistence for those with dependents and $21 for those with no dependents. The rental allowance is paid only when quarters on the military reservation are *not provided. The base pay for a lieutenant colonel is $320.83* a month with $120 a month rental allowance for those with dependents and $63 for subsistence for those with dependents. The corresponding figures for those without dependents are $105 and $21 a month. The professional qualifications for such specialists may be obtained from the Office of The Surgeon General, Washington, D. C.

GRADUATE TRAINING FOR MEDICAL OFFICERS

The Surgeon General's Office announces a new list of forty-five medical officers, including two colonels, seven lieutenant colonels, eight majors, eighteen captains and ten first lieutenants, *who have been accepted for graduate training in civilian institutions.* Among those listed with the training to be received are Norman E. Peatfield, Harvard University, public health; Joseph A. Lapiena, Springfield College, Mass., physical education and rehabilitation; Adam J. Rapalski, Johns Hopkins University, public health; John B. Logan, Garfield Memorial Hospital, Washington, D. C., intern training; Anthony V. Torre, Providence Hospital, intern training; George M. DiRienzo, Coney Island Hospital, Brooklyn, intern training; James O. Wall, Charles T. Miller Hospital, St. Paul, Minn., intern training; Louis J. West, University of Minnesota Hospital, Minneapolis, intern training; Alva E. Miller, University of California, psychiatry-neurology; Richard L. Bohannon, University of Southern California; internal medicine; Harold A. Myers, New York Polyclinic Medical School and Hospital, surgery; Adante A. B. D'Amore, Cook County Graduate School of Medicine, surgical technic; Lewis C. Shellenberger, Johns Hopkins University, public health; Earl G. Kingdon, Johns Hopkins University, public health; Spurgeon H. Neel, Johns Hopkins University, public health, and Charles C. Bruce, Johns Hopkins University, public health.

NAVY

POSTGRADUATE TRAINING

The following medical officers have been nominated to attend courses of instruction as indicated:

Comdr. Leonard J. Hahne, in Ophthalmology at Northwestern University Medical School, Chicago.

Comdr. Morton L. Lillie, in Dermatology and Syphilology at the Skin and Cancer Unit of the New York University College of Medicine.

Lieut. Comdr. William C. Cantrell, in Children's Orthopedics at the University of Iowa College of Medicine.

Lieut. Howard W. Hill to a Residency in Surgery at the Naval Hospital, Oakland, Cal.

Lieut. (jg) Adolphus W. Dunn in the Basic Science Course at the Army Medical Center, Washington, D. C.

Lieut. (jg) Tom C. Hardy, MCR, in Anesthesiology at the Cleveland Clinic.

Lieut. (jg) Stephen R. Mills, Jr., a Residency in Internal Medicine at the Naval Hospital, Bethesda, Md.

Lieut. (jg) Robert E. Mitchel, a Residency in Internal Medicine at the Naval Hospital, San Diego, Cal.

Lieut. (jg) Ernest A. Sneddon, a Residency in Anesthesiology at the Naval Hospital, Philadelphia, Pa.

Lieut. (jg) George J. Taylor III, a Residency in Obstetrics and Gynecology at the Naval Hospital, San Diego, Cal.

Lieut. (jg) Sydnor T. Withers, in Dermatology and Syphilology at the Skin and Cancer Unit of New York University College of Medicine.

NEW REGULAR OFFICERS

The following reserve medical officers have transferred to the Medical Corps of the Regular Navy: Comdr. Donald G. MacKinnon, Visalia, Calif., and Lieuts. (jg) Donald R. Davis, Madison, Wis., and Dennis P. McCarty, Delaplane, Va.

PERSONALS

Captains Jesse D. Jewell of Portland, Ore., and Robert H. Collins of Arlington, Va., now on the retired list, have voluntarily requested recall to active duty and will be ordered respectively to the Naval Recruiting Station in Portland and the Naval Recruiting Station in Philadelphia.

Comdr. Alan D. Grinstead of Raleigh, N. C., has recently accepted an appointment as aviation psychologist in the Medical Service Corps of the Regular Navy.

AWARDS AND COMMENDATIONS

Captain Albert R. Behnke

The Secretary of the Navy recently awarded a Letter of Commendation to Captain Albert R. Behnke, MC, Research Executive Officer at the Naval Medical Research Institute, Bethesda, Md. The Letter reads in part as follows: "For exceptionally meritorious service while attached to the Experimental Diving Unit, Washington, D. C., and while participating in experiments conducted at that station during the period 1937 through 1939. Captain (then Lieutenant) Behnke contributed outstandingly to rescue and salvage work of the Navy, by his study and perseverance and courage in experimental diving. His knowledge and leadership in applying the newly developed technic to the science of deep sea diving received international recognition and reflect the highest credit on himself and the United States Naval Service."

Medical News

(Physicians will confer a favor by sending for this department items of news of general interest: such as relate to society activities, new hospitals, education and public health. Programs should be received at least two weeks before the date of meeting.)

ARIZONA

Harlow Brooks Clinical Conference.—The Ninth Harlow Brooks Memorial Navajo Clinical Conference will be held at Sage Memorial Hospital, Ganado, August 30 to September 1. Out of state speakers include: Henry M. Benning, Santa Barbara, Calif., Relationship of Diabetes to Infectious Hepatitis; Harvey E. Billig Jr., Los Angeles, Role of Cervical Sympathetics in Facial Neuralgia; E. Forrest Boyd, Los Angeles, Intestinal Obstruction Due to Gall Stones; Warren H. Cole, Chicago, Hyperthyroidism; Felix Cunha, San Francisco, Case Histories in Gastro-Enterology; Alfred C. Emmel, Mount Vernon, N. Y., Rh Factor in Surgery and Obstetrics; Alfred E. Gallant, Los Angeles, Closed Reduction of Difficult Fractures Involving the Lower Extremity; David P. Findley, Omaha, Treatment of Cervicitis; Benjamin H. Grimm, Sidney, Neb., Problems of a General Practitioner; L. Dale Huffman, Los Angeles, Case of Chronic Adhesive Pericarditis with Calcification; Lucius W. Johnson, San Diego, Calif., The Surgeon in the Hospital; Newell Jones, Los Angeles, Childhood Allergy; Fred L. Knowles, Fort Dodge, Iowa, Fractures of the Os Calcis; Chester H. MacKay, Los Angeles, Nephroptosis or Movable Kidney; Joseph F. Montague, New York, Troubles We Don't Talk About; Thomas B. Noble Jr., Indianapolis, Method for Reduction of Operative Mortality and Postoperative Morbidity Following Cholecystectomy; Daniel P. Quiring, Ph.D., Cleveland, Collateral Circulation, Anatomical Aspects; James P. Rigg, Grand Junction, Colo., The Paranasal Sinuses; Buell E. Sprague, Los Angeles, Sleeve Anastomosis of the Small Gut; Philip Thorek, Chicago, Vagotomy and the Ulcer Problem, and George C. Tyler, Los Angeles, Current Procedures in Treatment of Rectal Cancer.

CONNECTICUT

Award Trudeau Medal.—Rudolph J. Anderson, Ph.D., professor of chemistry at Yale University, has been awarded the Trudeau Medal of the National Tuberculosis Association for outstanding research concerning tubercle bacilli. The presentation was made by Dr. David R. Lyman, superintendent of Gaylord Farm Sanatorium, Wallingford, one of Connecticut's five state hospitals for the care and treatment of tubercular patients.

Annual Clinical Congress at New Haven.—The Connecticut State Medical Society's twenty-third Clinical Congress will be held in cooperation with the Yale University School of Medicine, New Haven, September 14-16. Morning sessions will be held in the auditorium of the law school and afternoon sessions in the New Haven Hospital and Yale Medical School. The subjects for discussion include diabetes, infections of the urinary tract, allergy, deafness, surgery of the hand and surgery in peripheral vascular disease.

ILLINOIS

Personal.—Dr. Donaldson F. Rawlings, Galesburg, has been appointed chief of the Division of Maternal and Child Health, Illinois Department of Public Health, succeeding Dr. Ruth E. Dunham, Chicago, who resigned to accept a commission in the U. S. Public Health Service.

Encephalitis in Cook County.—Seven mild cases of encephalitis have been reported since July 1 in the southwest section of Cook County. Dr. Edward A. Piszczek, county health officer, has asked the Des Plaines Valley Mosquito Abatement district for specimens of mosquitoes with which to make a laboratory check.

Chicago

Research on Poliomyelitis.—The National Foundation for Infantile Paralysis has awarded a research grant of $6,080 to the University of Illinois College of Medicine for the period from July 1 to December 31. The grant will be used for electromyographic studies and studies in electrical stimulation of muscles of patients with poliomyelitis. The studies will be carried out by Dr. Andrew C. Ivy, vice president in charge of the Chicago Professional Colleges, and Dr. H. Worley Kendell, head of the department of physical medicine.

The Morton Memorial.—Northwestern University has received a gift of $70,000 from Sterling Morton of Lake Forest, chairman of the board of the Morton Salt Company. Although no restriction was placed on the gift, it is expected that the trustees will add it to the more than $2,000,000 bequeathed to Northwestern in 1940 by the late Mrs. Joy Morton. Terms of Mrs. Morton's will provided that the bequest be used for medical research and for the erection and endowment of the Morton Memorial Hospital, which the university plans to build on the Chicago campus. Construction of the hospital has been delayed by abnormally high building costs.

Personals.—Dr. Sol. B. Kositchek has retired from the Commonwealth Edison Company's staff after thirty-five years of service. At a luncheon in his honor Dr. Kositchek was presented with a radio, a camera and a basket of thirty-five roses as farewell gifts from his friends.——Dr. Stephen Rothman, professor of dermatology, University of Chicago School of Medicine, delivered four lectures on "Physiology of the Skin" on June 16-18 before graduate students in dermatology at Columbia University College of Physicians and Surgeons, New York.——Major General Paul R. Hawley, formerly Chief Medical Director of the Veterans Administration, now of Chicago, addressed the Biological Sciences and Hospital groups at the recent annual meetings of the Special Libraries Association in Washington on "Social Responsibility for Medical Care."

MARYLAND

Dr. Bronk New President of Johns Hopkins.—Detlev W. Bronk, Ph.D., director of the Eldridge Reeves Johnson Foundation for Medical Physics and professor of biophysics of the University of Pennsylvania, Philadelphia, has accepted the presidency of The Johns Hopkins University, effective Jan. 1, 1949. He will succeed Dr. Isaiah Bowman, president since 1935, now retired. Dr. Bronk went to the University of Michigan as instructor in physiology and while there was awarded a Ph.D. He went to England in 1929 as a National Research Council fellow and on returning became professor of biophysics and director of the Johnson Foundation at the University of Pennsylvania. He was coordinator of research in the Air Surgeon's Office during the war and he has been a member of the Board of Scientific Directors of The Rockefeller Institute for Medical Research. Since 1946 Dr. Bronk has been chairman of the National Research Council.

MASSACHUSETTS

Harvard Enlarges Teaching and Research Programs.—The Department of Public Health Practice of the Harvard School of Public Health will institute, in September, enlarged teaching and research programs in cancer control and in the public health aspects of mental health. The objectives of the cancer control program will be administrative, epidemiologic and statistical research in cancer and the training of cancer control administrators. The project is financed by a $40,000 grant from the U. S. Public Health Service and $6,909 from the Massachusetts Division of the American Cancer Society. The cancer control officers will receive basic public health training followed by specialized cancer teaching under the direction of the cancer control staff of the Harvard School of Public Health and in cooperation with the Cancer Institute at the New England Deaconess Hospital, Boston, the Division of Cancer of the Massachusetts Department of Public Health, the Peter Bent Brigham Hospital, Boston, and the Massachusetts Division of the American Cancer Society. The sum of $230,000 has been received from the Grant Foundation for a five year investigation of certain problems of community mental health and a broadened teaching program. The first community service center and research unit under the project will be established in Wellesley in October. Groups participating in the community mental health program are the department of social relations at Harvard University, the Harvard Medical School, the Massachusetts General Hospital, the Wellesley Community Mental Health Committee and the Harvard School of Public Health.

MICHIGAN

Annual Postgraduate Conference.—The annual Postgraduate Conference of the Michigan State Medical Society will be held in Detroit at the Book-Cadillac Hotel, September 22-24. Among the guest essayists are: Dr. Frank H. Lahey, Boston; Waltman Walters, Rochester, Minn.; Richard W. TeLinde, Baltimore; Haven Emerson, New York; Lester H. Dragstedt, Chicago; Alexander Brunschwig, New York, and Stanley P. Reimann, Philadelphia. There will be extensive exhibits. Doctors of medicine from neighboring states are invited. To insure hotel accommodations for the session, write Dr. E. C. Texter, Chairman of Housing Committee, 1005 Stroh Bldg., Detroit.

Pasteurization Law in Effect.—Michigan's new milk pasteurization law, which became effective July 1, requires that all milk sold to the retail trade, as well as milk, cream, skim milk and other dairy products used in manufacture of butter, cheese and cottage cheese, be pasteurized. A previous law had provided the same safeguard for ice cream. Milk and dairy products sold at the farm where they are produced or used on the farm where they are produced are exempt from the law. The state department of health has prepared an illustrated wall card of instructions for home pasteurization of milk which can be had without charge by writing the department at Lansing 4.

MISSOURI

Jackson County Health Forum.—Seven free lectures will be presented by the Hospital Auxiliaries of the accredited hospitals of Jackson County at the Municipal Auditorium, Kansas City, on the third Wednesday of each month at 8:15 p. m. The program is as follows:

September 15. E. W. Alton Ochsner New Orleans, Gallbladder and Stomach Complaints.

October 20, George E. Shambaugh Jr., Chicago, A New World for the Hard of Hearing.

November 17, Bayard T. Horton, Rochester, Minn., Migraine Headaches.

January 12, Cyril M. MacBryde, St. Louis, Diabetic Treatment.

February 16, Willard O. Thompson and M. Edward Davis, Chicago, Change of Life Problems in Men and Women.

March 16, O. Spurgeon English, Philadelphia, What Is Psychosomatic Medicine?

April 20, Morris Fishbein, Chicago, What Makes a Successful Marriage?

NEW YORK

Study of Hospital Expenses.—The financial difficulties of hospitals and the implications for future hospital maintenance, operation and service will be analyzed during the next year by Columbia University under a contract with the New York State Joint Hospital Survey and Planning Commission under a $60,000 allotment from the state. Columbia will examine the financial structure of the hospital system in New York State, analyze relative costs for various classes of patients and responsibilities of government for financial aid to hospitals, and prepare a report. The study will be directed by Eli Ginzberg, associate professor of economics at Columbia's School of Business. Professor Herbert Klarman of the department of economics at Brooklyn College will serve as assistant director for the study.

New York City

Research Fellowships Available.—Two appointments for research fellows in medicine for studies in the field of metabolic and degenerative diseases are available in the New York Post-Graduate Hospital. Opportunity for ward studies, postgraduate courses and outpatient clinics is included. The salary is $3,000 per annum. Qualifications are graduation from a Grade A medical school and three years' approved hospital training in medicine and allied fields. Male and female applicants are acceptable. Applications should be addressed to Dr. John D. Currence, New York Post-Graduate Medical School and Hospital, 303 East 20th Street, New York 3.

Free Penicillin for Venereal Disease.—Penicillin-oil-beeswax for intramuscular injection is now available from the New York City Health Department to local physicians, without charge, for the treatment of venereal disease. Penicillin will be supplied in recommended dosages after verification of the diagnosis. The department will continue to distribute arsenical drugs and bismuth compound. In order to obtain penicillin or the arsenicals an official case report must be on file with the department of health for each patient given a diagnosis and/or under treatment and contact information submitted on case report forms (417V), which are obtainable from the Bureau of Social Hygiene, Department of Health, 125 Worth Street, New York 13.

PENNSYLVANIA

Publish Case Histories for Clinical Pathologic Conference.—In preparation for the clinicopathologic conferences on the program of the centennial meeting of the Medical Society of the State of Pennsylvania, October 3-7, the six case abstracts to be discussed are being published in the state journal in advance. The Committee on Scientific Work has planned three conferences for the afternoons of Tuesday, Wednesday and Thursday. Publication at this time will enable physicians to become familiar with the case histories and record their own diagnosis before the meetings.

Philadelphia

Honorary Degrees Conferred.—At the Commencement Exercises June 4 of The Jefferson Medical College of Philadelphia, honorary degrees were conferred on the following physicians: Doctor of Science—Dr. John H. Gibbon, Media, professor of surgery and clinical surgery, emeritus, The Jefferson Medical College, and Dr. LeRoy A. Schall, professor of otology and laryngology and head of the department, Harvard Medical School, Boston.

Faculty Promotions.—Dr. Joseph O. Crider, assistant dean, has been promoted to professorship in physiology at the Jefferson Medical College of Philadelphia. A graduate of the University of Virginia Department of Medicine, Charlottesville, 1912, he was from 1913 to 1930 on the staff of University of Mississippi School of Medicine, University, Miss., which he left as dean and professor of physiology and histology. He then joined the teaching staff at Jefferson Medical College as assistant dean and associate professor in the physiology department. Dr. Nicholas A. Michels, associate professor in the anatomy department, has been promoted to professorship in anatomy. He became a member of the teaching staff at Jefferson Medical College in 1929. Andrew Jackson Ramsay, Ph.D., has been promoted from associate professor to professor of histology and embryology. He joined the teaching staff in 1936.

Pittsburgh

Orthopedic Lectures.—Lectures for orthopedic technicians are being given at the Mellon Institute, the University of Pittsburgh School of Medicine and several local hospitals September 20-26. The conference is being sponsored by the department of orthopedic surgery of the University of Pittsburgh School of Medicine, with the assistance of the Sarah Mellon Scaife Foundation Fellowship on Orthopedic Appliances at the institute. The course will be presented through lectures, demonstrations of actual devices on patients, discussions and field trips. A collection of exhibits will be set up by the staff and participants in the conference near the Institute's auditorium. The registration fee is $5.

TEXAS

Visiting Professor Frazier.—Dr. Chester N. Frazier, professor of dermatology and syphilology, Harvard Medical School, and director, dermatology service, Massachusetts General Hospital, Boston, has been appointed visiting professor of dermatology and syphilology at the University of Texas Medical Branch, Galveston. Dr. Frazier will continue to supervise research work on the etiology of cardiovascular syphilis which was inaugurated under his direction at the University of Texas Medical Branch. He will also assist in the supervision of residency training in dermatology and syphilology at the John Sealy Hospital.

Memorial to Dr. Singleton.—Friends of the late Dr. Albert O. Singleton, formerly professor of surgery at the University of Texas Medical Branch, Galveston, have contributed a bronze memorial plaque which will be placed near the entrance to the Special Surgical Unit of the John Sealy Hospital, which has recently been completed as a result of plans made by Dr. Singleton. The Special Surgical Unit is designed primarily for the accommodation of patients requiring plastic or neurosurgery. It contains fifty-six beds, two operating rooms, clinic and x-ray facilities.

UTAH

Annual State Meeting.—The annual meeting of the Utah State Medical Association will be held September 2-4 at Cedar City, under the presidency of Dr. John C. Hubbard, Price. Guest speakers include: Arild E. Hansen, Galveston, Texas, Preventive and Therapeutic "Musts" in Infantile Diarrhea; Ovid O. Meyer, Madison, Wis., Treatment of Subacute Bacterial Endocarditis; Earl D. McBride, Oklahoma City, Differential Diagnosis in Low Back Pain; Edwin J. DeCosta, Chicago, Prolonged Labor; Theodore R. Miller, New York, Symptomatology of Gastric Cancer; Fred W. Wittich, Minneapolis, Emergency Treatment of Allergic Diseases; John F. Patton, St. Louis, Bladder Neck Obstructions in Women and Children; Alfred J. Cone, St. Louis, Difficulties in Swallowing; Gustaf E. Lindskog, New Haven, Conn., Carcinoma of the Lung; Guy V. Pontius, Chicago, Management of Carcinoma of the Colon, and Charles L. Lowman, Los Angeles, Basic Principles of Functional Restoration in Poliomyelitis. Guest speakers will participate in panel discussions in surgery and medicine Thursday afternoon, another in surgery and one in obstetrics and gynecology Friday afternoon. At the annual banquet, September 3 at 7 p. m. in the El Escalante Hotel, Dr. Thad P. Sears, Ft. Logan, Colo., will speak on "Basic Physics and Hazards of the Atomic Bomb."

WYOMING

Appoint State Health Department Director.—Dr. Franklin D. Yoder, Cheyenne, started in his new position as director of the state department of public health August 1. Dr. Yoder finished a year's postgraduate work in public health at the University of California in June. He practiced in Cheyenne from 1940 to 1947, except for three years' service with the Army Air Force during World War II. He is also the new secretary of the Wyoming State Board of Medical Examiners.

GENERAL

Biologic Photographers Meeting.—The Biological Photographic Association, Inc., will hold its annual meeting in Philadelphia, September 8-10, at Houston Hall, University of Pennsylvania. There will be an exhibition of prints, color transparencies and motion pictures in the field, organized symposiums and demonstrations. Further information may be secured from the Secretary, Biological Photographic Association, University Office, Magee Hospital, Pittsburgh 13, Pa.

Plague Infection in Rodents.—According to the U. S. Public Health Service, plague infection was reported in Rio Arriba County, New Mexico, under date of June 8 in a pool of 145 fleas from one prairie dog, shot May 26 near the junction of State Highway 95 and U. S. Highway 84 and also in a pool of 20 fleas from another prairie dog, shot May 27 on a ranch 13 miles west of Parkview. In Douglas County, Washington, plague infection was found in a pool of 196 fleas from 30 meadow mice trapped May 5 about 9 miles north of Farmer.

World Congress on Poliomyelitis.—A world organization to fight infantile paralysis on a global scale was approved unanimously by delegates of the First International Conference on Poliomyelitis held in New York, July 12-17, according to the National Foundation for Infantile Paralysis. Known as the World Congress on Poliomyelitis, it will serve as a clearing house for pooling and channeling to member countries knowledge of the disease and its treatment. A committee of ten from the United States and one each from England, Denmark, the Netherlands, Brazil and Chile, was named to work on details of organization.

Regional Meetings of Pathologists.—The first of two regional postgraduate meetings of the College of American Pathologists will be held at the Baker Hotel, Dallas, Texas, September 6-7. Hematology and blood bank problems will be the major subjects for discussion. Among the speakers will be Dr. Paul A. Owren, Lillehammer, Norway, "Newer Concepts of Blood Coagulation." At the Northeastern Regional Meeting to be held at Massachusetts General Hospital, Boston, September 18, the topics include clinical pathology, physiology, hematology, neuropathology, diagnosis of tuberculosis, virology and problems encountered in the smear diagnosis of cancer.

Centennial of Science Association.—One World of Science will be the keynote of the American Association for the Advancement of Science centenary to be held in Washington D. C. September 13-17. Scientific sessions will be held in the morning and evening hours. The morning scientific sessions include sections on genes and cytoplasm, Tuesday; world health problems, Wednesday, and food and nutrition, Thursday; evening sessions will include addresses on the theory of the nerve impulse; oxygen isotopes in nature and in the laboratory; science, psychiatry, survival; science and UNESCO on Wednesday, and the human frontier and medical research on Thursday.

Mississippi Valley Societies.—The annual meeting of the Mississippi Valley Medical Society will be held at Springfield, Ill., September 29 to October 1, at the Hotel Abraham Lincoln. Wednesday's program will feature lecturers from St. Louis. Speakers at the banquet September 30 include: Drs. Percy E. Hopkins, Chicago; Robert Mueller, St. Louis, and Nathaniel G. Alcock, Iowa City. Round table luncheons are planned for the last two days. There is no registration fee. Dr. Morris Fishbein, Chicago, Editor of The Journal, will give a two hour instruction course in medical writing in the afternoon, September 29, before the Mississippi Valley Medical Writers and Editors Association. Informtion may be secured from Dr. Harold Swanberg, Secretary, 209-224 W. C. U. Building, Quincy, Ill.

Obstetricians, Gynecologists and Abdominal Surgeons. The American Association of Obstetricians, Gynecologists and Abdominal Surgeons will hold its fifty-ninth annual meeting at The Homestead, Hot Springs, Virginia, September 9-11, under the presidency of Dr. Robert D. Mussey, Rochester, Minn. Those speaking by invitation include: Frank R. Lock, Winston-Salem, N. C., Early Diagnosis of Carcinoma of the Cervix with Emphasis on Routine Biopsy; Conrad G. Collins, New Orleans, Ectopic Pregnancy—Mortality and Morbidity Factors; William T. Kennedy, New York, Know the Pelvis; James P. Hennessy, New York, Report on Cesarean Sections, and L. Marshall Harris, Captain (M.C.) U.S.N., Great Lakes, Ill., Role of Penicillin in Obstetrics. The Foundation Prize Thesis will be read by Dr. Barnet Delson, Brooklyn, "Non-Neoplastic Ovarian Cysts—Their Relation to Spiral Arteries in the Human Ovary." The Joseph Price Oration will be delivered by Dr. O'Donel T. D. Browne, Dublin, Ireland, on "The Treatment of Dysmenorrhea by Nerve Section." The banquet will be held September 10 at 7:30 p. m. with Dr. Raymond B. Allen, Seattle, as speaker.

Incidence of Poliomyelitis.—The reported incidence of poliomyelitis in the United States increased from 982 cases the week ending July 31 to 1,215 for the week ending August 4, according to the U. S. Public Health Service. For the corresponding weeks of 1947 and 1946, respectively, 169 and 911 cases were reported. The five year median for the week is 391. Currently, about 43 per cent of the cases were reported in three states: California, 224; North Carolina, 212, and Texas, 82. Increases were also reported in about half of the other states. A total of 5,798 cases has been reported to date, as compared with 1,742 in 1947, 4,171 in 1946 and a five year median of 2,439 for the corresponding period.

The following named states have reported more than 100 cases up to July 31: North Carolina, 1,103; California, 1,027; Texas, 960; New York, 190; Ohio, 177; Iowa, 164; South Carolina, 124; Nebraska, 122; Oklahoma, 119; Florida, 116; Virginia, 113; Illinois, 113, and New Jersey, 103. The total to date for the six New England States is 45 cases. No case has been reported to date in Rhode Island, and only 1 case in Nevada.

There is apparently no indication of extension of the epidemic area in North Carolina—the central and west central parts of the state—although a few scattering cases are being reported in counties outside the epidemic area. To date cases have been reported in 83 of the 100 counties in the state. In Texas the largest numbers of cases have been reported in Harris, Hildago, Cameron, Galveston, Nueces, Tarrant and Bexar counties, with scattering cases beginning to be reported toward the central and northern parts of the state. In California the largest number of cases are being reported in the southern part of the state.

Reports for the week ended August 7 show cases increased from 1,215 to 1,239, the smallest numerical and percentage increase since early in June. Incidence declined in all three of the states reporting the largest number of cases—North Carolina, California and Texas. Only 8 states reported increases of 10 or more. Cases reported to date total 7,039, as compared to 1,967 in 1947, 5,450 in 1946 and a five-year median of 2,913 for the corresponding period.

CORRECTION

Test for Adrenal Cortical Insufficiency.—The second sentence of the summary in the article by Thorn and others in The Journal, July 17, page 1009, should read as follows: "It is suggested that a decrease of 50 per cent or more in the circulating eosinophils or an increase of 50 per cent or more in the urinary uric acid–creatinine ratio indicates adequate adrenal cortical reserve."

Marriages

Walter Spray Rothwell, New Bedford, Mass., to Miss Barbara Chapman of Boston, in New York, March 20.

Thomas Oliver Coppedge Jr., Winston-Salem, N. C., to Miss Mary Raboteau Council of Lake Waccamaw, April 10.

Francis Record Whitehouse, Lynchburg, Va., to Miss Elizabeth Watts of Bryan, Texas, April 2.

Edward William Mullin, Syracuse, N. Y., to Miss Helen Josephine Burke of Brooklyn, May 22.

Barkley Beidleman, Hanover, Pa., to Miss Statia Helen McNeese of Bassfield, Miss., in March.

Allison Reeves Morgan to Miss Constance Marion Nigels, both of Miami, Fla., in April.

Everett C. Sutter, Staten Island, N. Y., to Miss Helen C. Wolfe of Stapleton in May.

Joseph J. Szal, Minersville, Pa., to Miss Mildred Buriak of Shamokin, May 30.

Deaths

Albert Ira Robbins ✠ New Haven, Conn.; born in Malden, Mass., Nov. 22, 1914; University of Vermont College of Medicine, Burlington, 1939; interned at Grace Hospital; began active duty as a first lieutenant in the medical corps, Army of the United States in April 1941; discharged with the rank of captain in September 1944; formerly assistant resident in orthopedics at the Children's Hospital in Boston and fellow in orthopedics at Boston City Hospital; served as resident in orthopedics at the Hospital for Special Surgery, New York; appointed clinical instructor in surgery at the Yale University School of Medicine; assistant director of the Westchester Cerebral Palsy Association in New York; affiliated with the Newington (Conn.) Home for Crippled Children and the Veterans Administration Hospital in Newington; on the staff of the Grace-New Haven Community Hospital; certified by the National Board of Medical Examiners; died April 14, aged 33, of carcinoma of the lung.

William Augustus Downes, Newburgh, N. Y.; born in Crockett, Texas, Dec. 2, 1872; Columbia University College of Physicians and Surgeons, New York, 1895; for many years on the faculty of his alma mater; formerly instructor in anatomy and surgery at Cornell University Medical College in New York; member of the American Surgical Association and the Society of Clinical Surgery; fellow of the American College of Surgeons; served during World War I; at one time surgeon for the New York National Guard; consulting surgeon, St. Luke's, Babies, Memorial and Manhattan State hospitals, the Hospital for Special Surgery, New York Nursery and Childs Hospital and New York Infirmary in New York, the United Hospital, Port Chester and the Stamford (Conn.) Hospital; formerly assistant chief surgeon of the New York Central Railroad; died May 10, aged 75, of coronary occlusion.

William Robert Morrison ⊕ Billings, Mont.; born in Corunna, Ontario, Canada, March 2, 1876; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1899; member of the American Academy of Ophthalmology and Otolaryngology; specialist certified by the American Board of Ophthalmology and the American Board of Otolaryngology; served during World War I; colonel, medical reserve corps, U. S. Army; served as president of the Montana Reserve Officers Association; past president of the hospital medical staffs of St. Vincent and Deaconess hospitals; consultant in ophthalmology for the Burlington Railroad and the Northern Pacific Beneficial Association; died May 2, aged 72, of pulmonary edema.

Myron William Clift, Midland, Mich.; born in Bay City, Mich., April 14, 1883; University of Michigan Medical School, Ann Arbor, 1905; member of the American Medical Association; fellow of the American College of Physicians; specialist certified by the American Board of Radiology, Inc.; formerly an associate professor of roentgenology at Detroit Medical College; consultant and officer in charge of the Army X-Ray School in Paris, France, during World War I; served on the staffs of the Receiving, Wyandotte and Shirley hospitals in Detroit; for many years chief of radiology at Hurley Hospital, Flint; radiologist at Midland Hospital, where he died May 7, aged 65.

Cornelius Francis McCarthy, Auburn, N. Y.; born on Aug. 15, 1866; University of Vermont College of Medicine, Burlington, 1890; member of the New York State Association of Public Health Laboratories, American Medical Association and of the Syracuse Academy of Medicine; past president of the Cayuga County Medical Society, of which he had been historian; served on the city milk commission for two terms; formerly health officer of Batavia; a member and secretary of the board of managers of Cayuga County Laboratory from 1924 to 1937; on the staffs of Auburn City Hospital and Mercy Hospital, where he died May 5, aged 81, of uremia.

John Calvin Morrison Brust ⊕ Syracuse, N. Y.; born in Syracuse, Oct. 16; 1905; Syracuse University College of Medicine, 1929; associate professor of clinical surgery (proctology) at his alma mater; certified by the National Board of Medical Examiners; formerly a fellow at the Mayo Foundation in Rochester, Minn.; specialist certified by the American Board of Surgery; served in the medical corps of the U. S. Naval Reserve during World War II; assistant proctologist at the University Hospital and Free Dispensary and Syracuse Memorial Hospital; died May 14, aged 42, of a fracture of the skull received in an accident.

Fenton Taylor, New York; born in Orange, N. J., Nov. 22, 1887; Columbia University College of Physicians and Surgeons, New York, 1913; member of the American Medical Association and the New York Academy of Medicine; in 1916 joined the British Army and won the British Military Cross for gallantry in action with the first Leicestershire Brigade in France; later served in France with the American Red Cross and the American Expeditionary Forces, from which he was discharged as a major; on the staffs of Doctors Hospital and the Southampton (N. Y.) Hospital; died May 26, aged 60, of heart disease.

Cornelius O. Anderson ⊕ Concordia, Kan.; Northwestern University Medical School, Chicago, 1903; died April 30, aged 74, of paralysis agitans.

Albert Stewart Barr ⊕ Ann Arbor, Mich.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1909; member of the American Academy of Ophthalmology and Otolaryngology; specialist certified by the American Board of Ophthalmology; served during World War I; from 1919 to 1922 on the staff of University Hospital; on the staff of St. Joseph's Mercy Hospital, where he died April 27, aged 65, of melanotic sarcoma.

Charles E. Beck ⊕ Portland, Pa.; Medico-Chirurgical College of Philadelphia, 1893; an affiliate fellow of the American College of Surgeons; past president of the Northampton County Medical Society; president of the Portland borough council for many years; served on the school board, as postmaster and as vice president of the Portland National Bank; affiliated with the Easton (Pa.) Hospital and the General Hospital of Monroe County in East Stroudsburg; died April 29, aged 80, of arteriosclerosis.

Claude Conley Bell, Denver; Denver College of Medicine, 1901; member of the American Medical Association; served during World War I; on the visiting staffs of the Mercy Hospital, St. Luke's Hospital, St. Joseph's Hospital and the Presbyterian Hospital, where he died April 30, aged 73, of coronary thrombosis.

Edmond Elmore Bohlender, Dayton, Ohio; Medical College of Ohio, Cincinnati, 1894; served on the staff of St. Elizabeth Hospital; died April 26, aged 80, of coronary disease.

William Oscar Bonser ⊕ Toledo, Ohio; University of Toronto Faculty of Medicine, Toronto, Canada, 1911; affiliated with the Maumee Valley, Mercy and Toledo State hospitals; died April 22, aged 59, of coronary occlusion.

John Ruskin Bradley, Spencerport, N. Y.; Cornell University Medical College, New York, 1907; died May 3, aged 68.

William M. Bradshaw ⊕ New York; Columbia University College of Physicians and Surgeons, New York, 1909; fellow of the New York Academy of Medicine; medical director of the Mutual Life Insurance Company of New York; at one time adjunct attending physician at Bellevue Hospital; died in the Roosevelt Hospital May 1, aged 64, of arteriosclerotic heart disease.

Milledge Thompson Brodie, Charlotte, N. C.; Meharry Medical College, Nashville, Tenn., 1927; school physician of Johnson C. Smith University; affiliated with the Good Samaritan Hospital, where he died April 29, aged 51, of hypertensive cardiovascular disease and cerebral thrombosis.

Herman Bryan, Wooster, Ohio; University of Pennsylvania Department of Medicine, Philadelphia, 1901; for many years a medical missionary in China; died May 9, aged 73, of chronic myocarditis.

William Henry Burke, Middletown, N. Y.; Bellevue Hospital Medical College, New York, 1882; died in the Horton Hospital April 20, aged 88, of a fractured femur received in a fall.

Thomas Jefferson Calhoun ⊕ Carrollton, Texas; University of Texas School of Medicine, Galveston, 1923; member of the American Academy of Dermatology and Syphilology, Southern Medical Association and the Texas Dermatological Society; chairman of the staff of the City-County Hospital in Dallas; served during World War I; died April 11, aged 57, of coronary thrombosis.

Darwin Bryan Childs, Tulsa, Okla.; University of Tennessee College of Medicine, Memphis, 1931; died April 24, aged 41, of phenobarbital intoxication.

Lyman W. Childs, Cleveland; Western Reserve University Medical Department, Cleveland, 1894; past president of the American Association of School Physicians; for many years supervisor of public health in Cleveland schools; in 1943 received the William A. Howell Medal for distinguished service in the field of school health; died in Fort Lauderdale, Fla., April 23, aged 80, of ruptured arteriosclerotic aneurysm of aorta.

Wallace Berwell Christian, St. Louis; Howard University College of Medicine, Washington, D. C., 1905; member of the staffs of the Homer G. Phillips Hospital, where he served as superintendent, St. Mary's Infirmary and the People's Hospital, where he died April 21, aged 74, of heart disease.

William David Chrisman, Eagle Rock, Calif.; Northwestern University Medical School, Chicago, 1896; died in Wadsworth Hospital, Sawtelle, April 21, aged 76, of a hip fracture received in a fall, cerebral hemorrhage and pneumonia.

Amos Watson Colcord ⊕ Clairton, Pa.; College of Physicians and Surgeons, Baltimore, 1893; served as president of the school board and of the Clairton Library Board; formerly surgeon for the Carnegie-Illinois Steel Corporation; died April 30, aged 84, of carcinoma of the stomach.

George James Connor ⊕ Haverhill, Mass.; Maryland Medical College, Baltimore, 1909; chairman of the board of health; associated with Hale Hospital; died in the Phillips House, Boston, April 18, aged 61, of carcinoma of the lung.

Richard Lloyd Cook, Washington, D. C.; University of Virginia Department of Medicine, Charlottesville, 1904; served in France during World War I; formerly senior surgeon in the U. S. Public Health Service reserve; at one time affiliated with the Veterans Administration Hospital in Outwood, Ky., and other Veterans Administration hospitals; served as a member of the Veterans Administration Disability Rating Board; found dead April 26, aged 69.

Frederick Aloysius Coughlin ⊕ Providence, R. I.; Johns Hopkins University School of Medicine, Baltimore, 1908; fellow of the American College of Surgeons; served during World War I; on the staffs of Rogers Williams, St. Joseph's and Rhode Island hospitals; died in St. Francis Hospital in Miami Beach, Fla., April 19, aged 65, of hypertensive cardiovascular disease.

John Stephen Couret ⊕ New Orleans; Tulane University of Louisiana School of Medicine, New Orleans, 1929; member of the American Society of Clinical Pathologists; on the staff of Hotel Dieu; died April 15, aged 42, of heart disease.

James Scott Covey, Culleoka, Tenn.; Vanderbilt University School of Medicine, Nashville, 1893; member of the American Medical Association; affiliated with the King's Daughters' Hospital in Columbia, where he died April 27, aged 79, of uremia, following an operation.

William Benjamin Crawford, Goldsboro, N. C.; Bellevue Hospital Medical College, New York, 1886; died April 20, aged 87, of arteriosclerotic heart disease.

Michael A. Cunningham, Janesville, Wis.; Rush Medical College, Chicago, 1896; member of the American Medical Association; affiliated with the Mercy Hospital; died April 23, aged 84, of heart disease.

Anna Keith Davenport, Hartford, Conn.; Medical College of the State of South Carolina, Charleston, 1903; Syracuse University College of Medicine, 1917; member of the American Medical Association; died in the Hartford Hospital April 22, aged 77, of carcinoma of the gallbladder.

John Rumsey Davies Jr., ⊕ Philadelphia; Jefferson Medical College of Philadelphia, 1913; specialist certified by the American Board of Otolaryngology; served in France during World War I; affiliated with Children's Heart, Pennsylvania, Chestnut Hill, Bryn Mawr (Pa.) and Abington (Pa.) Memorial hospitals; died in Blue Hill, Maine, April 22, aged 57, of pulmonary thrombosis.

Alvah Clark Dickson, Donelson, Tenn.; University of Nashville Medical Department, 1899; member of the American Medical Association; on the staffs of the Nashville General Hospital, St. Thomas Hospital and the Protestant Hospital, all in Nashville, where he died April 25, aged 70, of cerebral hemorrhage.

Gerry Lewis Esersky ⊕ Brooklyn; Tufts College Medical School, Boston, 1925; member of the American Urological Association; affiliated with the Beth El and Cumberland Street hospitals; died in St. Francis Hospital, Miami Beach, Fla., April 30, aged 47, of heart disease.

Frank J. Filz, Seattle; University of Southern California School of Medicine, Los Angeles, 1903; member of the American Medical Association; formerly a druggist; died April 17, aged 84, of cardiac failure.

Charles Louis Garvin, Palo Alto, Calif.; Cooper Medical College, San Francisco, 1895; served during World War I; formerly on the faculty of the University of Southern California School of Medicine, Los Angeles; died at the Palo Alto Hospital April 28, aged 79, of cerebral hemorrhage.

Reid Gilmore, Schenectady, N. Y.; Albany Medical College, 1900; member of the American Medical Association; affiliated with the Ellis Hospital; died April 28, aged 72, of arteriosclerosis.

David Irwin Glass, Louisville, Ky.; University of Louisville School of Medicine, 1927; member of the American Medical Association; served during World War II; died in St. Joseph Infirmary in April aged 44, of bilateral polycystic disease and uremia.

Clyde Oden Griffin, Lindsay, Calif.; University of Pennsylvania School of Medicine, Philadelphia, 1910; died April 8, aged 61.

Howard Hogan, Dallas, Texas; University of Edinburgh Faculty of Medicine, Scotland, 1933; member of the American Medical Association and of the American Society of Anesthetists, Inc.; served during World War II; formerly medical director of the Nepera Chemical Company, Yonkers, N. Y.; died April 20, aged 48, of carcinoma of the esophagus.

Joseph T. D. Howard, Falls Church, Va.; Georgetown University School of Medicine, Washington, D. C., 1889; at one time affiliated with the Indian Service and Veterans Administration; died April 15, aged 81, of uremia due to cardiovascular renal disease.

Edwin Lee Jones, Medical Inspector, Commander, U. S. Navy, Dallas, Texas; University of Texas School of Medicine, Galveston, 1903; entered the U. S. Navy in 1906 and retired July 1, 1936; died in U. S. Naval Hospital, Houston, April 17, aged 72, of cerebral thrombosis.

William Howard Kingston, Moira, N. Y.; Long Island College Hospital, Brooklyn, 1909; member of the American Medical Association; served as president of the board of education; formerly director of the Farmingdale (N. Y.) Bank and president of the Farmingdale Board of Education; served as health officer of Bombay and Moira; on the staff of the Alice Hyde Memorial Hospital in Malone, where he died April 16, aged 67.

Francis Evelyn Knowles, Coconut Grove, Fla.; College of Physicians and Surgeons, Baltimore, 1893; died in the Jackson Memorial Hospital, Miami, April 19, aged 79, of uremia, following an abdominal operation.

Frederick De Forest Lambert, Tyngsboro, Mass.; Boston University School of Medicine, 1900; Harvard Medical School, Boston, 1901; past president of the Middlesex North District Medical Society; on the staff of Lowell (Mass.) General Hospital; died April 20, aged 70, of coronary thrombosis.

Leonard Templeton Lane, Prichard, Ala.; University of Alabama School of Medicine, 1912; served in France during World War I; died in a hospital at Mobile, April 25, aged 63, of coronary occlusion, arteriosclerosis and diabtes mellitus.

Everard T. Lark ⊕ Columbia, Ill.; St. Louis University School of Medicine, 1902; president of the Monroe County Medical Society; on the staff of the Deaconess Hospital in St. Louis; died April 20, aged 67, of coronary occlusion.

Ota Carita Loud, Palm Beach, Fla., University of Arkansas School of Medicine, Little Rock, 1916; died April 18, aged 57.

John Stoddard McCormick ⊕ Albany, N. Y.; Albany Medical College, 1914; also a graduate in pharmacy; fellow of the American College of Surgeons; attending surgeon at St. Peter's Hospital, where he died April 22, aged 58, of chronic peritonitis and diverticulitis of the colon.

Philip Daniel McGinnis, Joliet, Ill.; Rush Medical College, Chicago, 1900; member of the American Medical Association; past president of the Will-Grundy Counties Medical Society; health officer; served on the staff of St. Joseph Hospital, where he died April 18, aged 72, of uremia.

Herbert Bruce McIntire ⊕ Cambridge, Mass.; University of the City of New York Medical Department, 1882; died April 21, aged 90, of arteriosclerotic heart disease.

Leon Feinson Muldavin ⊕ New York; L.R.C.P., London, and M.R.C.S., England, 1935; assistant adjunct surgeon at Beth Israel Hospital, where he died April 25, aged 37, of acute lymphatic leukemia.

Martin Gillespie Neely ⊕ Birmingham, Ala.; University of Virginia Department of Medicine, Charlottesville, 1925; specialist certified by the American Board of Pediatrics; past president of the staff of the Children's Hospital; for many years chief of the pediatric department of the Employees' Hospital of the Tennessee Coal, Iron and Railroad Company in Fairfield; died April 23, aged 48, of carcinoma of the nasopharynx.

Elmer Hiram Parker, River Falls, Wis.; Chicago Medical College, 1891; fellow of the American College of Surgeons; died in Lake Wales, Fla., April 19, aged 84, of arteriosclerotic heart disease.

Gilman Caldwell Paynter, Falfurrias, Texas; University of Illinois College of Medicine, Chicago, 1943; member of the American Medical Association; interned at the Naval Hospital in Norfolk, Va.; formerly a resident at the Swedish Covenant Hospital in Chicago; served in regular navy during World War II; died May 1, aged 29, of infantile paralysis.

Myron Hopkins Powelson, Zanesville, Ohio; Ohio State University College of Medicine, Columbus, 1926; member of the American Medical Association; entered the Mayo Foundation as a fellow in medicine in April 1929 and left in January 1930; died May 1, aged 43.

David Benjamin Rotman ✠ Chicago; Chicago College of Medicine and Surgery, 1916; clinical professor of psychiatry at the University of Illinois College of Medicine; president elect of the Illinois Psychiatric Society; served during World War I; resident assistant and senior physician at the Chicago State Hospital from 1917 to 1923; director of the Psychiatric Institute, Municipal Court; died May 30, aged 55, of coronary thrombosis.

John Chandler Shirley ✠ Huron, S. D.; Northwestern University Medical School, Chicago, 1911; fellow of the American College of Surgeons; past president of the South Dakota State Medical Association; on the staff of the Sprague Hospital; district surgeon for the Chicago and North Western Railway; local surgeon for the Great Northern Railway; died in St. Mary's Hospital, Rochester, Minn., April 30, aged 63, of hepatic insufficiency and infectious hepatitis.

Ben Durham Spears ✠ Wauchula, Fla.; Georgia College of Eclectic Medicine and Surgery, Atlanta, 1914; past president of the DeSoto-Hardee-Highlands-Charlotte Glades Counties Medical Society; died April 25, aged 56, of heart disease.

Robert Caldwell Strode, West Branch, Mich.; Washington University School of Medicine, St. Louis, 1905; head of District Health Unit number 2; found dead April 5, aged 69, of acute endocarditis.

Andrew Jackson Strong, Norfolk, Va.; Leonard Medical School, Raleigh, N. C., 1906; affiliated with the Norfolk Community Hospital, where he died April 22, aged 69, of acute cardiac dilatation.

Willard W. Swarts ✠ Three Rivers, Mich.; Medical College of Ohio, Cincinnati, 1896; formerly practiced in Auburn, Ind., where he served as county health officer and secretary of the city board of health; died April 24, aged 75, of cerebral hemorrhage.

John S. Thompson, Gravette, Ark. (licensed in Arkansas in 1903); member of the American Medical Association; died in Bentonville April 28, aged 82, of coronary occlusion.

Silas Terry Yeatts, Floyd, Va.; Lincoln Memorial Univercity Medical Department, Knoxville, Tenn., 1910; president of the Floyd County Medical Society; a member of the board of health; served as mayor and member of the town council; died in a hospital at Roanoke April 27, aged 60, of hypertensive heart disease.

William M. York, Huntington, W. Va.; Eclectic Medical Institute, Cincinnati, 1907; at one time state senator; served as commissioner of finance, health and taxation; formerly practiced in Williamson, where he had been mayor and member of the city commission; died April 23, aged 67, of coronary occlusion.

KILLED IN ACTION

Lieut. Comdr. Herbert C. Brokenshire
(MC) U.S.N.R., 1896-1944

Lieut. (jg) Frank Hight Gerard
(MC) U.S.N.R., 1917-1945

Lieut. George T. Ferguson
(MC) U. S. Navy, 1914-1944

Herbert Cecil Brokenshire, Winchester, N. H.; Cornell University Medical College, New York, 1924; interned at the Methodist Episcopal Hospital in Brooklyn; at one time affiliated with the U. S. Public Health Service; served as a medical missionary in the Philippines, where he was director of the Davao Mission Hospital from 1926 to 1941; served during World War I began active duty as a lieutenant commander in the U. S. Naval Medical Reserve in 1941; reported missing following the capture of Manila in 1941 and later reported a prisoner of the Japanese; awarded the American Defense Service Medal (Base clasp), Asiatic Pacific Area Campaign Medal and Purple Heart; the Bronze Star Medal awarded posthumously; killed in the South China Sea Oct. 24, 1944, aged 48, as the result of the sinking of a Japanese ship on which he was being transported while a prisoner of war.

Frank Hight Gerard, Haverford, Pa.; Hahnemann Medical College and Hospital of Philadelphia, 1943; interned at the Hahnemann Hospital in Philadelphia; began active duty as a lieutenant (jg) in the medical corps of the U. S. Naval Reserve, on Oct. 10, 1944; killed in action off Okinawa May 27, 1945, aged 28.

George Theodore Ferguson, Lieutenant (MC), U. S. Navy, Wausau, Wis.; Marquette University School of Medicine, Milwaukee, 1938; interned at the Kansas City General Hospital in Kansas City, Mo.; appointed to the medical corps of the U. S. Navy as a lieutenant (jg) in August 1938; graduated from the U. S. Naval Medical School in 1939; from September 1939 until November 1941 served in China as medical officer on the U. S. S. *Wake,* on the Yangtsze River Patrol, and in the battles of Manila and Corregidor in World War II; captured by the Japanese and held as a prisoner of war for two and one-half years in prison camps in the Philippines; on duty with the Fourth Marines; promoted to first lieutenant; died Oct. 24, 1944, aged 30, when the Japanese prison ship on which he was confined was bombed.

Maternity Service Under the National Health Act

When a government, even with the best intentions, tries to regulate the affairs of its citizens from the cradle to the grave, it is sure to make many mistakes. In a letter to the *Times* Sir William Gilliatt, president of the Royal College of Obstetricians and Gynecologists, points out that the childbearing women of this country have been misled by being led to expect that under the National Health Service a physician experienced in obstetrics will be available for all who require medical help during labor. Under the National Health Service Act the maternity services come under three separate administrative bodies: (1) regional hospital boards and boards of governors of teaching hospitals for consultants and maternity nurses in hospitals, (2) local authorities for domiciliary midwives, (3) executive councils for nurses and for practitioners undertaking obstetric work. The college has consistently deprecated this division of control. The care of the pregnant woman, whether at home, at the clinic or in the hospital, is a responsibility which cannot be discharged with the maximum safety, with respect to the two lives at stake, if shared between different administrative bodies. The greater part of our maternity service has been and can safely be left in the hands of the midwives, provided that experienced practitioners are available for antenatal consultations, for abnormalities arising during labor or in the puerperium and for postnatal examinations. The public has been told that every expectant mother can have the services of a physician who undertakes maternity work. But it is doubtful whether this promise can be implemented. If it is, there will be little place for the fully trained midwives, who have borne the responsibility for 75 per cent of domiciliary births. If it is not, the midwives will be still needed, but removal of their responsibility will seriously hamper recruitment to their ranks.

The college has always advocated that there should be a list of practitioners who have had experience in maternity work after qualification to be called in for midwives' emergencies. Practitioners entitled to have their names placed on this list are: (1) those who have held a resident obstetric appointment and (2) those similarly well qualified by long experience in practice. But it appears now that any practitioner can undertake maternity work under the act. Guidance should be given to local committees on the principles of selection of general practitioner-obstetricians for an approved list. None has been given by the Ministry as to the obstetric experience desirable. The president therefore asks that the Ministry of Health should undertake a comprehensive review of the results of the maternity service of the National Health Service.

Science and Socialism

The socialization of medicine is only part of the Government's plan to socialize as many industries as possible. However, English moderation and instinct for a middle course have saved us from some extremes which would probably have materialized in other countries under a socialist government. The government has complete control of the medical profession, but it has compromised on many of the demands made by medical negotiators, even to the dissatisfaction of its more extreme supporters. While taking over all the voluntary hospitals, excepting a few small ones controlled by religious bodies, it has left untouched the autonomy of the medical schools attached to hospitals. Similar restraint is shown in the first annual report of the Advisory Committee on Scientific Policy, which has just been published. This committee was appointed by the government. The general effect of their recommendations on governmental scientific research is that the independence and initiative of the research councils should be preserved, but that executive departments, to whose work science can contribute, should assume a more positive role in the organization and direction of research required for their purposes, and in supervising its application. In some departments, particularly in those responsible for socialized industries, it might be advantageous to appoint an advisory council to assist the minister in formulating departmental scientific policy. No attempt should be made to concentrate responsibility for all governmental scientific research on a minister, for this would be a step in creating a ministry of science and would intensify the old cleavage between science, administration and policy.

With regard to scientific man power, it had been estimated in 1946 that the number of qualified scientists was about 55,000 and that the minimum demand by 1950 would be for 70,000 and by 1955 for 90,000. We could not expect more than 64,000 by 1955 unless the prewar output of 2,500 a year were raised to 5,000. Happily the latest figures from the universities indicate that this level has been reached. These figures apply to pure scientists. The figures are less assuring as to applied scientists.

The Danger to Children from Contact with Tuberculous Persons

The Joint Tuberculosis Council has made a report on the protection of organized groups of children from the risk of infection by adults suffering from tuberculosis. It gives examples of a teacher of children and a woman working in a day nursery who were found to have advanced phthisis. The Council makes the following recommendations: 1. No person with pulmonary tuberculosis should be allowed to accept employment which will involve contact with organized groups of children until the disease has been certified as arrested. 2. All whose duties bring them into close contact with organized groups of children should undergo a medical examination, including roentgen examination of the chest, and should hereafter have a roentgen examination annually while so employed. 3. If any employee is found to be suffering from pulmonary tuberculosis, employment should cease at once and not be resumed until two consecutive medical certificates have been submitted, one certifying that the disease is no longer active and the other that the improvement has been maintained at least six months after the date of the first certificate. 4. When employment is resumed, similar certificates should be submitted at three month intervals for a year and at six month intervals for a further two years.

Prevention of Injury in Air Crashes

The Air Registration Board has had under consideration the problem of how to increase the chances of survival of passengers in air crashes. In the *Journal of the Royal Aeronautical Society* the secretary, Mr. R. E. Hardingham, says that although 90 per cent of accidents are not caused by lack of airworthiness, but by error of judgment or by weather, there is still much to be done in the matter of design. The avoidance of physical injury to the occupants in a crash is of prime importance if there is to be much hope of escape. Head injuries are the commonest, and Mr. Hardingham advocates the provision of seats facing aft. To avoid injuries to pilots he suggests that all instruments should be sunk into a fascia board of smooth metal, and that flush fittings should be used wherever possible to avoid dangerous knobs and projections. Fire is the greatest risk, and bag fuel tanks are much safer than integral tanks. They should be fitted in the wings, as far as possible from the fuselage, but not so far out as to render them likely to be ruptured in a one wheel or sideslip landing. They should certainly not be located where they would be broken by an undercarriage collapse.

Medicopolitical Criticism

A representative referred to the sense of disappointment and frustration shown in considerable correspondence in the *British Medical Journal* and moved that a special committee be set up to obtain full information about the conduct of the profession's case during 1948. The chairman of council replied by attacking the mover and seconder of the motion for bringing it forward without notice. They protested too much when they said that it had not been brought forward in criticism of the council, and they implied that he, as chairman, had not disclosed to the representative body the things that had taken place. He repudiated that absolutely. This call for a postmortem examination could serve no useful purpose. To say that the profession is dissatisfied with the conduct of affairs means merely "that you are dissatisfied with your own action. We are undertaking to cooperate in the service and can only do the best we can for it and the public." After further discussion the motion was lost by a large majority. Though formally only a motion for an inquiry, it represented the dissatisfaction of the section of the association who disapproved of the decision to accept the service. The deputy chairman of the representative body condemned the motion as a heresy hunt, a call for a postmortem examination of the events of the last few months, which would do no good.

ITALY

(From Our Regular Correspondent)

Florence, June 26, 1948.

Medical Treatment of Dysthyreosis

The recent Congress of the Italian Association for Internal Medicine reviewed the medical treatment of dysthyreosis, the presentation of which was trusted to Professors Meneghetti (University of Padua), Patrassi, Beretta and Bastai. Prof. Meneghetti pointed out that new research has been done on the relation between iodine and thyroid. It was observed that after removal of the thyroid, the iodine of the tissues may determine phenomena of hyperthyroidism. From that the supposition was derived that diiodotyrosine may be formed also in the extrathyroid tissues. Research on radioactive iodine has defined the modality of the thyroid secretion as follows: The secreting cell elaborates the diiodotyrosine, which is poured into the follicle, and there the synthesis of the thyroxin and of the thyroglobulin may be accomplished. Successive proteolytic enzymes may divide the thyroglobulin, and the products of this division may pass through the walls of the follicle and be poured into the blood.

Present knowledge of the pharmacology of radioactive iodine holds prospects of its usefulness in hyperthyroidism. The drugs whose antithyroid action has been observed in recent years are numerous, but only a few have a specific action. Three groups may be considered: thiourea and its derivatives (thiouracil and others); aminothiazole and its derivatives; the aminobenzene drugs (para-aminobenzoic acid, sulfonamide drugs and others). The product preferred now is thiouracil, particularly benzyl thiouracil.

Professor Patrassi discussed thyroid hormones. Thyroxin is not the only genuine thyroid hormone. The thyroglobulin of the colloid substance has globulinic structure and condenses in itself various amino acids. The thyroglobulin does not pour over into the blood stream, and it may not, therefore, be considered as the circulating thyroid hormone. According to recent views, there does not exist a unique thyroid hormone, but various active iodized groups, which vary in composition and activity.

The treatment of hypothyroidism centers in the use of total thyroid extracts, especially dry ones, and of thyroxin. The efficacy of the dry extracts is indisputable; the only difficulty is the correct dosage; a good criterion consists in the percentage of the organic iodine. The parenteral route is preferred for the administration of thyroxin. In the treatment of hypothyroidism the dry thyroid is preferred to the thyroxin. The problem of dosage is much disputed, and this applies to the dry thyroid as well as to thyroxin; but firmly established is the principle to cling to the minimum amount required for obtaining the clinical effect, and dosage may be gradually increased until this effect is reached. The thyroid medication may be combined with other hormone preparations if one keeps in mind that other endocrine organs may take part in the genesis of myxedema, and particularly in cases of thyroresistant myxedema. The results of properly practiced thyroid opotherapy are the most brilliant among those obtained in endocrinopathy.

The risk of thyroid medication consists foremost in the production of hyperthyroidism, of anginoid, hypoglycemic and hypoadrenal crises. The person suffering from myxedema, cautiously treated, may survive to a very old age.

Professor Beretta emphasized that hyperthyroidism has a cyclic course, consisting of exacerbations and of remissions which occasionally may be so prolonged as to simulate recovery. Frequently the results of treatment may coincide with this periodicity of thyroid activity; therefore, in order to pass definite judgment on the real efficiency of the treatment one may consider only late results.

One must keep in mind that the basedowian syndrome does not have a single pathogenesis, being associated not only with hyperthyroidism but with various other factors. Consequently, the treatment of toxic diffuse goiter (Basedow's disease) cannot be standardized, but should be oriented according to the pathogenesis; for example, primary hyperthyroidism and thyrotoxicosis of nodular goiter must be treated in a different way than thyrotoxicosis of diffuse goiter.

The medicinal treatment consists essentially of the administration of iodine, of diiodotyrosine, of vitamins and of derivatives of thiourea. These last products bring about a decisive thyroinhibitory action. Although the volume of the goiter and the exophthalmos remained generally unchanged, in nearly all cases treated, a symptomatic remission was obtained which was so pronounced that it might be defined as a clinical recovery. However, two important questions remained: the duration of the remission after the drug was discontinued and the frequency of toxic manifestation with which it may be associated. Of particular interest is the granulocytopenia. The remission may continue for as long as two years, and any recurrences are always sensitive to renewal of treatment. Toxic manifestations do not exceed 2 per cent of the cases treated and have a tendency to become less frequent when less toxic drugs (methylthiouracil, propylthiouracil, thiobarbituric compounds) are used. If the experience of the next few years confirms the results already obtained with the thiourea derivatives, these new drugs may prove as effective as roentgen ray or surgical treatment.

Professor Bastai discussed particularly the so-called myxedema heart and the condition of the vascular system in this disease. Degenerative changes may occur, and these, together with the hypercholesteremia, may explain the possible occurrence of coronary sclerosis or even a cardiac infarct.

The frequent anemic syndrome of hypothyroid patients is due to the fact that the bone marrow is sensitive to the stimulating action of thyroid substances.

To determine rational criteria of treatment, one must distinguish between the various clinical and pathogenetic forms of hyperthyreosis. In mild forms, small doses of iodine for several weeks appear useful (5 to 10 drops of Lugol's solution per day), with weekly intervals between the weeks when treatment is given. In medium severe and grave forms it is necessary to differentiate between toxic diffuse goiter (Basedow) and nodular toxic goiter. According to the speaker, nodular toxic goiter does not respond to medical or roentgen ray treatment; it represents a clear indication for thyroidectomy. The hyperthyroid syndrome of diffuse goiter, on the contrary, is susceptible to efficacious treatment with the derivatives of thiourea, as well as by roentgen ray and by surgery.

Medical Economics

NUMBER OF LIVING PHYSICIANS BY STATES

FRANK G. DICKINSON, Ph.D.
Director, Bureau of Medical Economic Research
Chicago

According to a tabulation from the punch cards being developed by the Bureau's staff,[1] there were 199,755 living physicians in the United States as of about June 1, 1948. Cards have not yet been punched for June graduates of medical colleges. All living physicians for whom cards have been prepared are included in this tabulation by states. It is known that some of them are retired, some are not in practice and some are employed by federal, state and local health agencies. As the Bureau's punch card system nears completion subsequent tabulations will present breakdowns showing the number in each of these groups.

The Bureau started on this operation more than a year ago and hopes to have all the punch cards complete early in 1949. As all the information recorded to date in our punch cards has been taken from the records of the Directory Department, our work cannot move along any faster than the vast clerical operation of the Directory Department in preparing its final copy for the new American Medical Directory. When finally completed, our punch cards will contain some information which will not appear in the Directory and vice versa.

Approximate Number of Living Physicians in the United States, by States, May-June 1948

State	No. Living	State	No. Living
Alabama	2,238	Nebraska	1,625
Arizona	802	Nevada	198
Arkansas	1,750	New Hampshire	727
California	16,069	New Jersey	6,585
Colorado	2,202	New Mexico	508
Connecticut	3,261	New York	30,970
Delaware	439	North Carolina	3,377
District of Columbia	4,130	North Dakota	467
Florida	2,931	Ohio	10,091
Georgia	3,145	Oklahoma	2,206
Idaho	470	Oregon	1,852
Illinois	13,307	Pennsylvania	14,633
Indiana	4,396	Rhode Island	1,039
Iowa	2,933	South Carolina	1,530
Kansas	2,223	South Dakota	517
Kentucky	2,683	Tennessee	3,349
Louisiana	3,080	Texas	7,621
Maine	1,010	Utah	831
Maryland	3,696	Vermont	689
Massachusetts	9,102	Virginia	3,306
Michigan	7,127	Washington	2,811
Minnesota	4,263	West Virginia	1,839
Mississippi	1,525	Wisconsin	3,873
Missouri	5,352	Wyoming	252
Montana	514		
Total			199,755

We present the accompanying table for publication at this time because comparable data on the number of physicians in each of the states have not been published since the 1942 Directory. This table is offered at the present time as an aid to those who have need for over-all data on the number of living physicians in the several states. Owing to unrecorded deaths and interstate migrations in addition to some inevitable duplications and omissions of punch cards prior to a final check, there are a number of small errors of unknown magnitude in this list which will be removed before the punch card system is completed. As additional tabulations and breakdowns will be published as soon as we complete them, we trust that interested readers will postpone any requests for additional data.

At this stage of our operations, one important statistical fact emerges. The (approximate) number of living physicians in the United States is now 17 per cent greater than the 170,163 shown in the 1940 A. M. A. Directory; the population of the United States has increased only 12 per cent since 1940. Because the number in each state as shown in this table is only approximately correct we are not ready to present the increase or decrease in the number of living physicians in each state. This is another way of saying that the total for the United States, 199,755, is a more reliable estimate than the number shown for any one state.

Medical Motion Pictures

FILM REVIEWS

The Diagnosis of Tuberculosis with an Improved Culture Medium. 16 mm., black and white, sound, 722 feet, (1 reel), showing time twenty minutes. Produced in 1948 by and procurable on loan from: U. S. Public Health Service, Communicable Disease Center, 605 Volunteer Bldg., Atlanta 3.

This film presents an improved medium (Loewenstein) for the clinical diagnosis of tuberculosis, which may show growth in two weeks. Minute details of preparation of the medium, of handling of sputum, including its concentration, and of all steps involved are presented clearly and instructively. Impressive, among other features, are the fine reproductions of colonies and the stress on gross colony identification.

Photography is excellent and photomicrography is technically very satisfactory. The narration is fair to good.

This film can be recommended for showing to phthisiologists, bacteriologists, technicians, physicians and medical students. The procedure is simple enough to be employed in any well equipped laboratory.

Demerol and Pudendal Block. 16 mm., color, silent, 550 feet, (1 reel), showing time fifteen minutes (run at sound speed). Prepared in 1947 by Lees M. Schadel Jr., M.D., Department of Obstetrics, with the Cooperation of the Department of Anesthesiology, Hahnemann Medical College and Hospital, Philadelphia. Produced by News Reel Laboratory, Philadelphia, through a grant from the Winthrop Chemical Company, Inc. Procurable on loan or purchase from the author, 918 Medical Arts Bldg., 16th and Walnut Sts., Philadelphia 2.

This film presents a method of producing obstetric analgesia and complete perineal anesthesia by a combination of meperidine and scopolamine, and bilateral pudendal nerve block. The nerve supply to the perineum is reviewed and the landmarks used in blocking the pudendal nerves demonstrated. The technic of injection is well shown and the resulting area of analgesia outlined. The appearance of spontaneous respiratory efforts immediately following delivery would seem to indicate that a minimal degree of respiratory depression of the infant is produced by this method. The film should be of interest to obstetricians, anesthetists, interns and general practitioners. The photography is excellent.

Cervicitis, Etiology, Diagnosis and Treatment. 16 mm., color, sound, 1,700 feet, (1 reel), showing time forty-seven minutes. Prepared in 1946 by Bela C. Balas, M.D. and Herbert E. Schmitz, M.D., Department of Gynecology, Loyola University Medical School, Mercy Hospital, and Cook County Hospital, Chicago. Produced by the Medical Film Guild, New York, through a grant for postgraduate instruction from the A. C. Barnes Co., New Brunswick, N. J. Procurable on loan from: The Medical Film Guild, 167 West Fifty-Seventh Street, New York 19.

This film is an attempt to illustrate the etiology, diagnosis and treatment of cervicitis. The first part of it presents history, importance of cervicitis, symptoms, etiology, pathogenesis, histology, bacteriology, diagnostic measures and classification. This part of the film is rather confusing because the information presented is incomplete in many instances.

Doubtful is the emphasis placed on the importance of cervicitis as a focus of infection in systemic disease and the consideration of pathogenic bacteria as part of the normal vaginal flora, or that leukorrhea is the earliest sign of cervical carcinoma.

The author's classification of cervicitis is quite original, consisting of four conditions: endocervicitis, erosions, eversions and cystic disease. This is confusing because erosions and cystic disease are ordinarily considered to be complications or sequelae of cervicitis. Erosions are often seen in patients who have no other evidence of cervicitis. Eversions are distortions of the cervical structure caused by lacerations.

---

[1] The punch cards have the same geographic coverage as the American Medical Directory. The approximate number of living physicians in Canada about June 1, 1948 was 14,015; Alberta 792, British Columbia 1,181, Manitoba 780, New Brunswick, 326, Nova Scotia 587, Ontario 5,649, Prince Edward Island 73, Quebec 4,015, Saskatchewan 607, Yukon 2 and Northwest Territories 3. Labrador had 2 living physicians and Newfoundland 122. There were 1,278 located in United States possessions and territories; 71 in Alaska, 73 in the Canal Zone, 4 in the Mid-Pacific Islands of Guam, Johnson, Midway, and Wake, 468 in Hawaii, 648 in Puerto Rico, and 14 in the Virgin Islands. In addition to these there were 1,279 graduates of American and Canadian schools temporarily located in foreign countries.

The latter part of the film is devoted to therapy, which is divided into four categories: thermal, tamponing (chemical), cautery and surgical. The tampon or chemical treatment of cervicitis with mild silver protein is "sandwiched" around the surgical presentation and takes up about half of the time allotted to therapy. The cautery technic illustrated is too radical and extensive for the general practitioner. It shows various patterns of cautery incision, such as "wagon wheel" and "gridiron." The incisions shown are approximately 0.5 cm. in width and 0.5 cm. apart, making the illustration misleading to a beginner. Puncture cautery and endocervical cautery are shown by photographing actual cautery demonstrations, although the latter are not clearly shown. Little information is given concerning the indications or contraindications for this type of treatment, and nothing is said by way of warning against subsequent and consequent cervical stenosis.

Surgical treatment is presented by photographing two actual Stürmdorf operations; however, the approximating stitches after tying the Stürmdorf stitch are not clearly shown. In one operation only one stitch is used on each side, and in the second operation no stitches are used.

The treatment for the cause of the infection seems to have been overlooked in the film. In many cases the treatment will be unsuccessful unless the cause of the cervicitis is ascertained.

The chart showing the value of mild silver protein in 168 patients does not rule out the possible beneficial effects of more simple treatment or the recovery that one can normally expect when no treatment is administered.

Several statements in the film, such as references to mild silver protein as being effective in a wide bacteriostatic spectrum (whatever this may mean), would be criticised by specialists in the field of gynecology. Also disputed would be the explanation of the effectiveness of mild silver protein: The commentator, with the aid of a schematic presentation, shows a stream of cellular particles soaked with mild silver protein, assuring the audience that they penetrate the surrounding tissue. This is grossly exaggerated. The discharge of particles from a tampon in simple solution may not necessarily be the same as that encountered in the body tissues. Chemical products of the body cells markedly influence free passage of such particles. The statistics given are misleading and prove practically nothing. Mild silver protein was referred to as related to the sulfonamide drugs and penicillin; it is not related either chemically or otherwise to these agents.

This production has a certain documentary value because of the photography illustrating cervical pathologic change. The chief criticism centers on the narration on the controversial subject of focal infection, together with the dubious use of the idea of a bacterial spectrum and of the adjective "bacteriostatic." Penicillin and sulfonamide drugs are not merely bacteriostatic. The picture showing gonococci would satisfy bacteriologists better, perhaps, if some of the organisms were shown as intracellular. The surgical sequence is well illustrated. There is considerable animation at the beginning of the film. The photography is excellent except for the photomicrographs, which are poorly done. This film cannot be regarded as something to provide "postgraduate instruction."

Army Medical Laboratories. F.B. No. 217. 16 mm., black and white, sound, 1,450 feet, (1 reel), showing time forty minutes. Produced in 1946-47 by the War Department. Procurable from the Army Surgeon of the Army area in which the request originates.

This film depicts in detail the organization of the Army Medical Laboratories and includes a brief history of the laboratory activities both in this country and in foreign theaters during World War II. It begins with the Surgeon General's Office and includes the Zone of the Interior, overseas installations and many detailed duties of the various laboratory units.

The film can be used for the purpose of orientation for the physician entering the Army, who can obtain an excellent idea of the scope of the medical laboratories.

Immunization. 16 mm., black and white, sound, 390 feet, showing time eleven minutes. Prepared by: Michael Heidelberger, Ph.D.; Yale Kneeland Jr., M.D., and Harry M. Rose, M.D., Department of Medicine, College of Physicians and Surgeons, Columbia University, New York. Produced in 1917 by and procurable on rental or purchase from: Encyclopaedia Britannica Films, Inc., 1150 Wilmette Ave., Wilmette, Ill.

An attempt is made to explain what immunization is and how protection against infectious disease is attained. Four mechanisms of immunity are shown, namely, the development of naturally acquired immunity, immunity against smallpox with cowpox virus and the method by which antipneumococcus serum is produced and used to bring about passive immunity. The last sequence explains the development of antitoxic immunity against diphtheria.

The film is suitable for senior high school students and adult education groups, assuming, of course, that it is preceded and followed by considerable explanation and elucidation. It is doubtful whether the junior high school student would be able to grasp the concepts of immunity set forth in this highly concentrated form.

The producers are certainly to be congratulated on covering this complex subject by explaining the general mechanism underlying the production of immunity in such an effective and generally accurate way. The photography is excellent, the animation is well done and the narration is clear.

It's in the Bag. 16 mm., color, sound, 550 feet (1 reel), showing time fifteen minutes. Prepared by the Public Health Nursing Division, Texas State Department of Health, Austin. Produced in 1948 by and procurable through the Division of Public Health Education, Texas State Department of Health, Austin.

This film portrays the skills and activities of the public health nurse in the promotion and restoration of health and in the prevention of disease, and use of the nursing bag. The bag serves as a portable workshop for the public health nurse in the performance of her duties, working with parent groups, participating in clinics, making school visits or visits to the home. The technics employed by the nurse are accurate and would be acceptable, dependent on the policy of the agency.

The film may well be used for interpreting the functions of the public health nurse and bag technic to student nurses, postgraduate nurses being trained in public health and for orientation of new staff nurses. If it is to be used with lay groups in helping them to understand community health activities, it should be supplemented by discussion led by a public health nurse.

Questions, discussion and demonstration should be coupled with the use of the film. Although there is a lack of continuity of scenes, this does not detract from the teaching value of the film. The photography and narration are well done.

The following 16 mm., color, silent motion pictures were prepared by Alfred H. Iason, M.D., Adelphi Hospital, Brooklyn. Produced by The Bergman Associates, Brooklyn. Procurable on loan or purchase from the author, 41 Eastern Parkway, Brooklyn.

Pedicled Fascia Lata Transplant for Incisional Hernia. 200 feet, showing time eight minutes. Produced in 1941.

This film shows a fairly good demonstration of the repair of an incisional hernia. The author points out the important anatomic structures as they present themselves. Some of these are not absolutely clear and may have been improved on by more adequate dissection of the rectus sheaths. This would have allowed for direct approximation and closure of the defect, obviating the necessity for the fascia lata pedicle graft transplant to the defect. However, the film should not be condemned on this basis because the technic as illustrated is certainly justified and has given excellent results in large hernias. In parts of the operation, the surgical field is not walled off very well.

In all the films, the author uses excessively large suture material and takes rather large bites with his mattress sutures, thus strangulating a great deal of tissue. The skin closures could be improved, as he leaves a considerable amount of raw surface and a portion of some of the wounds were gaping.

The photography is excellent and the exposure of the surgical field is good. The titles are clear.

Repair of Bladder Hernia. 410 feet (1 reel), showing time seventeen minutes. Produced in 1943.

The repair of two bladder hernias is demonstrated. The bladders are opened and a portion excised. If the bladder diverticulum has been asymptomatic no repair is indicated and the diverticulum can simply be left alone. If it has been symptomatic, it may be better to fix the inguinal hernia and then repair the bladder diverticulum at a later date. However, it is not a gross error in surgical technic if the operations are primarily performed for the bladder diverticulum. A little more care could have been exercised in removing the diverticula and handling the tissues. Since in the procedure demonstrated a loop of bowel could have been caught in the suture, it might have been better to have transfixed the hernial sac open. The last credit title, "Produced by Bergman Associates," is upside down.

Surgery of Direct Hernia. 250 feet, showing time ten minutes. Produced in 1947.

In this motion picture, the author demonstrates the opening of the transversalis fascia and the direct sac for treatment of a direct hernia. If this is the new treatment, the claim is not justified. The author states that all direct hernial sacs should be opened; however, this is questionable. Many surgeons are of the opinion that small sacs can be inverted and that instances of recurrence are no higher. This film gives a good demonstration of one method of fixing a direct hernia.

Modification of Wyllys-Andrews Operation for (Left) Inguinal Hernia. 350 feet, showing time fifteen minutes. Produced in 1939-1941.

The film opens with some excellent colored charts of the anatomy involved. The author demonstrates fairly well the entire method of herniotomy and points out the important anatomic structures as they appear in the operative field. The film could be improved if an adequate explanation of the Wyllys-Andrews operation were incorporated in the film and the modification were made clearer.

Medical Examinations and Licensure

COMING EXAMINATIONS AND MEETINGS

EXAMINING BOARDS IN SPECIALTIES

American Board of Anesthesiology: *Written.* Various Centers, Jan. 21, 1949. Final date for filing application is Oct. 1. *Oral,* Philadelphia, Oct. 10. Sec., Dr. Paul M. Wood, 745 Fifth Ave., New York 22.

American Board of Internal Medicine: *Written.* Oct. 18. Asst. Sec., Dr. W. A. Werrell, 1 W. Main St., Madison 3, Wis.

American Board of Neurological Surgery: *Oral.* Chicago, June 1949. Final date for filing application is Jan. 1949. Sec., Dr. W. J. German, 310 Cedar Street, New Haven, Conn.

American Board of Obstetrics and Gynecology: *Part I.* Various Centers, Feb. 4, 1949. Final date for filing application is Nov. 1. Sec., Dr. Paul Titus, 1015 Highland Bldg., Pittsburgh 1.

American Board of Ophthalmology: *Oral.* Chicago, Oct. 6. *Written.* Various Centers, January 1949. Sec., Dr. S. J. Beach, 56 Ivie Rd., Cape Cottage, Maine.

American Board of Otolaryngology: *Oral.* Chicago, Oct. 5-8. New York City, Spring, 1949. Sec., Dr. D. M. Lierle, University Hospital, Iowa City.

American Board of Pathology: Chicago, Oct. 8-9. Final date for filing application is Oct. 1. Sec., Dr. Robert A. Moore, 507 Euclid Ave., St. Louis.

American Board of Pediatrics: *Oral.* Seattle, Sept. 10-12. Atlantic City, Nov. 17-19. Sec., Dr. Lee F. Hill, 718 Royal Union Bldg., Des Moines, Iowa.

American Board of Plastic Surgery: Examinations are given in June and November of each year in the hometown of applicants. Sec.-Treas., Dr. Louis T. Byars, 400 Metropolitan Bldg., St. Louis, Mo.

American Board of Radiology: Nov. Final date for filing application is Sept. 1. Sec., Dr. B. R. Kirklin, 102-110 Second Ave., S.W. Rochester, Minn.

American Board of Surgery: *Written.* Various Centers, March 1949. Final date for filing application is Dec. 1. Sec., Dr. J. S. Rodman 225 S. 15th St., Philadelphia.

American Board of Urology: Chicago, Feb. 12-16, 1949. Final date for filing application is Sept. 1. Sec., Dr. Harry Culver, Route #13, Sunnyside Rd., Minneapolis 4.

BOARDS OF MEDICAL EXAMINERS

Alabama: *Examination.* Montgomery, June 28-30, 1949. Sec., Dr. D. G. Gill, 519 Dexter Ave., Montgomery.

Alaska: * *Examination.* Juneau, Sept. 7. Sec., Dr. W. M. Whitehead, Box 140, Juneau.

Arkansas: *Eclectic Examination.* Little Rock, Nov. 4. Sec., Dr. C. H. Young, 1415 Main St., Little Rock.

California: *Oral.* Los Angeles, Nov. 20-21. *Written.* Sacramento, Oct. 18-21. Sec., Dr. Frederick N. Scatena, 1020 N Street, Sacramento 14.

Connecticut: * *Examination.* Hartford, Nov. 9-10. Sec., Dr. Creighton Barker, 258 Church St., New Haven.

District of Columbia: * *Reciprocity.* Washington, Sept. 13. Sec., Commission on Licensure, Dr. G. C. Ruhland, 4130 Municipal Bldg., Washington, D. C.

Georgia: *Examination.* Atlanta, Oct. 12-13. *Endorsement.* Atlanta, Oct. 14. Sec., Mr. R. C. Coleman, 111 State Capitol, Atlanta.

Illinois: Chicago, Oct. 5-7. Supt., Dept. of Registration and Education, Mr. Fred W. Ruegg, Capitol Bldg., Springfield.

Indiana: *Examination.* Indianapolis, June 1949. Sec., Board of Medical Registration & Examination, Dr. Paul R. Tindall, 416 K. of P. Bldg., Indianapolis.

Iowa: * *Examination.* Des Moines, Dec. 6-8, *Endorsement.* Des Moines, Oct. 4. Sec., Dr. M. A. Royal, 506 Fleming Bldg., Des Moines.

Kansas: Topeka, Dec. 15-16. Sec., Board of Medical Registration & Examination, Dr. J. F. Hassig, 905 N. 7th St., Kansas City.

Louisiana: *Examination.* New Orleans, Dec. Sec.-Treas., Dr. R. B. Harrison, 1507 Hibernia Bank Bldg., New Orleans 12.

Maine: Portland, Nov. 9-10. Sec., Board of Registration of Medicine, Dr. Adam P. Leighton, 192 State St., Portland.

Maryland: *Examination.* Baltimore, Dec. 14-17. *Endorsement.* At the discretion of the Board. Sec., Dr. Lewis P. Gundry, 1215 Cathedral St., Baltimore.

Minnesota: Minneapolis, Oct. 19-21. Sec., Dr. J. F. DuBois, 230 Lowry Medical Arts Bldg., St. Paul 2.

Montana: Helena, Oct. 4-6. Sec., Dr. O. G. Klein, First Nat'l Bank Bldg., Helena.

Nevada: Carson City, Nov. 1. Sec., Dr. G. H. Ross, Industrial Bldg., Carson City.

New Hampshire: * Concord, Sept. 9. Sec., Board of Registration in Medicine, Dr. J. S. Wheeler, Room 107, State House, Concord.

New Jersey: *Examination.* Trenton, Oct. 19-22. Sec., Dr. E. S. Hallinger, 28 W. State St., Trenton.

New Mexico: * Santa Fe, Oct. 11-12. Sec., Dr. V. E. Berchtold, 141 Palace Ave., Santa Fe.

New York: *Examination.* Various Centers, Sept. 27-30. Sec., Dr. J. L. Lochner, Jr., 23 South Pearl St., Albany 7.

Ohio: *Examination.* Columbus, Dec. *Endorsement.* Columbus, Oct. 5. Sec., Dr. H. M. Platter, 21 W. Broad St., Columbus.

Oregon: * *Examination.* Portland, Jan. 1949. *Endorsement.* Oct. 15-16. Final date of filing application is Oct. 1. Exec. Sec., Mr. Howard I. Bobbitt, 608 Failing Bldg., Portland.

Pennsylvania: *Examination.* Philadelphia, Jan., 1949. Act. Sec., Mrs. M. G. Steiner, 351 Education Bldg., Harrisburg.

Puerto Rico: *Examination.* Santurce, Sept. 7-11. Sec., Mr. Luis Cueto Coll, 22 Purada, Box 3717, Santurce.

Rhode Island: * *Examination.* Providence, Oct. 7-8. Chief, Div. of Professional Regulation, Mr. Thomas B. Casey, 366 State Office Bldg., Providence.

South Carolina: *Endorsement.* Sept. 6. Sec., Dr. N. B. Heyward, 1329 Blanding St., Columbia.

Texas: Fort Worth, Nov. 4-6. Sec.-Treas., Dr. M. H. Crabb, 1305 Amicable Bldg., Waco.

Virginia: *Examination.* Richmond, Dec. 3-4. *Endorsement.* Dec. 2. Sec., Dr. K. D. Graves, 30½ Franklin Road, Roanoke.

West Virginia: Charleston, Oct. 4-6. Comm., Public Health Council, Dr. N. H. Dyer, State Dept. of Health, Charleston.

Wisconsin: * Madison, Jan. 11-13, 1949. Sec., Dr. C. A. Dawson, Tremont Bldg., River Falls, Wis.

Wyoming: *Examination.* Cheyenne, Oct. 4. Sec., Dr. G. M. Anderson, Capitol Bldg., Cheyenne.

District of Columbia: *Examination.* Washington, Oct. 18-19. Sec., Dr. G. C. Ruhland, 4130 Municipal Bldg., Washington, D. C.

Florida: *Examination.* Gainesville, Nov. 6. Final date for filing application is Oct. 25. Mr. M. W. Emmel, University of Florida, Gainesville.

Iowa: Des Moines, Oct. 12. Sec., Dr. Ben H. Peterson, Coe College, Cedar Rapids.

Michigan: *Examination.* Ann Arbor and Detroit, Oct. 8-9. Sec., Miss Eloise LeBeau, 1510 West Allegan St., Lansing.

Minnesota: *Examination.* Oct. 5-6. Sec.-Treas., Dr. Raymond N. Bieter, 105 Millard Hall, Univ. of Minnesota, Minneapolis.

Nebraska: *Examination.* Omaha, Oct. 5-6. Dir., Bureau of Examining Boards, Mr. Oscar F. Humble, Room 1009 State Capitol Bldg., Lincoln.

Oklahoma: Spring of 1949. Sec., Dr. Clinton Gallaher, 813 Braniff Bldg., Oklahoma City.

Oregon: *Examination.* Portland, Sept. 4. Sec., Basic Science Examining Committee, Dr. C. D. Byrne, Univ. of Oregon, Eugene.

South Dakota: *Examination.* Vermillion, Dec. 3-4. Sec., Dr. G. M. Evans, Yankton.

Tennessee: *Examination.* Memphis & Nashville, Sept. 20-21. Sec., Dr. O. W. Hyman, 874 Union Ave., Memphis.

Wisconsin: *Examination.* Madison, Sept. 25. Final date for filing application is Sept. 18. Sec., Prof. W. H. Barber, Scott & Watson Sts., Ripon.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Right of Osteopath to Issue Certificate of Commitment to State Mental Institutions.—The plaintiffs, regularly licensed practitioners of medicine, filed suit for an injunction to restrain the secretary of welfare from authorizing the entry of mental patients to state, semistate or licensed hospitals for mental diseases on certificates of persons licensed under the Act of 1909 to practice osteopathy but not licensed under the medical practice act of 1911. From a decree denying the relief asked, the plaintiffs appealed to the Supreme Court of Pennsylvania.

Under the mental health act of 1923, which requires that the commitment of a mentally ill person to a hospital for mental diseases shall be on certificate of two qualified physicians, it is provided that the term, "qualified physician," shall mean ". . . a physician who . . . has been licensed to practice medicine in this state. . . ." Is a duly licensed osteopath a "qualified physician" within the meaning of this statute? A study of the pertinent legislative enactments and court decisions, said the Supreme Court, clearly reveals that the licensure of physicians for the practice of medicine and for the practice of osteopathy, as originally established and ordained by the legislature and as continued down to present day, rests on two separate, distinct and independent systems.

Prior to 1909 court decisions in the state definitely indicated a distinction between the practice of osteopathy and the practice of medicine. In 1909 the osteopathic practice act was enacted, and it provided, among other things, "that nothing contained in this act shall be construed as affecting the so-called practice of medicine." Thus, said the Supreme Court, the legislature plainly indicated its positive intent that those licensed thereunder were not licensed to practice *medicine* as that term had been judicially recognized and was then statutorily employed. Two years later the medical practice act of 1911, which in effect was a codification of existing statutory law relative to the practice of medicine, was enacted. Section 13 thereof provides: "The provisions of this act shall not apply either directly or indirectly, by intent or purpose to affect the practice of . . . osteopathy." Here, again, the legislature affirmatively evidenced its manifest policy and intent that the licensure of osteopaths or osteopathic physicians should not carry with it the right to practice medicine. Continuing, the Supreme Court said that with this statutory law relative to the practice of medicine and the practice of osteopathy thus developed in this state, there arose in 1921 the case of Commonwealth v. Dailey, 75 Pa. Sup. 510, in which the question presented was "whether an osteopathic physician duly licensed by the Osteopathic [State] Board is entitled under the law to engage *in* the general practice of medicine." In answering that question in the negative the superior court said: "Osteopaths are empowered to diagnose and treat diseases by employing osteopathy. Their privileges are not affected by the acts relating to the practice of medicine; but the right to practice medicine is not conferred upon those licensed under the Act of 1909, and its supplements, relating to osteopathy; and the fact that materia medica, therapeutics and other branches taught in medical schools are also imparted at the osteopathic college cannot extend the right of osteopaths to practice medicine."

Within two years of the foregoing clear and unmistakable judicial pronouncement the legislature passed the mental health act of 1923, wherein, as already stated, a "qualified physician" is specifically defined as ". . . a physician who . . . has been licensed to practice medicine in this state. . . ." What else could the legislature have possibly meant than that an osteopath or osteopathic physician is not qualified to certify a mentally ill person for commitment to a mental hospital?

Such, concluded the Supreme Court, must have been the legislature's understanding of its cognate statutes in the premises when it came to enact the statutory construction act of 1937. In that act there is clearly evidenced an intent that an already existing distinction between the practice of medicine and the practice of osteopathy was meant *to* be continued. Thus, Section 601 declares that an "osteopath" is "an individual licensed under the laws of this Commonwealth to practice osteopathy" and that a "physician" is "an individual licensed under the laws of this Commonwealth to engage in the practice of medicine and surgery in any or in all of its branches."

It happens, however, that in 1941 the legislature amended Section 1 of the medical practice act of 1911 by adding thereto two paragraphs the effect of which was to enlarge the field of "medicine and surgery" so as automatically to constitute "osteopathy" a branch of the practice of medicine. From that, the learned court below concluded: ". . . one designated a physician and licensed [under the Act of 1909] to diagnose and treat all types and conditions of diseases, albeit by osteopathic methods, is nevertheless licensed to practice a healing art and thus licensed to practice medicine." That deduction is not only a *non sequitur* but also an obvious anachronism, said the Supreme Court. The question here is what the legislature meant in 1923 by the phrase, "licensed to practice medicine in this state," as used in the mental health act of that year. The inescapable answer is that osteopaths were not so licensed, no more than were dentists or pharmacists whose licensure and regulation, just as in the case of the osteopath, is by virtue of respective independent statutes and not by the determinative medical practice act. The increased and increasing use of materia medica and therapeutics by osteopaths or osteopathic physicians and their continued encroachment on the field of medicine by the expansion of their theories, studies and practices must not be allowed to obscure the sole question in this case. The act of 1941 is in no sense an amendment of the mental health act of 1923, nor was it intended to be. Indeed, the latter act's definition of a "qualified physician" never has been amended.

In support of the claim that an osteopath is qualified to act as a committing physician under the mental health act, the defendant points to the fact that there is in this state an osteopathic hospital for "mental health patients . . . under the supervision of the department of welfare" and "licensed" by the Commonwealth. The issuance of a license for the particular hospital, said the Supreme Court, is readily understandable when it is borne in mind that the department of welfare of the Commonwealth, in reliance on opinions of the Attorney General has been treating osteopathic physicians and their institutions as if osteopaths were duly licensed under the medical practice act of 1911 to practice medicine. With those opinions, we manifestly do not accord. Yet, the fact is that it is those very opinions on which the defendants fundamentally base their present contention. We are unaware, however, of any instance where opinions of executive or administrative officers have been considered binding on the judiciary when called on to decide a justiciable controversy.

Nor is the fact that osteopaths have been permitted by various statutes to perform certain functions which, historically, have attached to the practice of medicine (e.g., the signing of death certificates) of any materiality to the present question, continued the court. A legislative grant to certain groups of the privilege of performing specific medical services does not carry with it a right to the unrestricted privilege of practicing medicine as defined by the medical practice act of 1911. Section 12 of the osteopathic act, which requires osteopathic physicians to observe and be subject to "all state and municipal regulations relating to the control of contagious diseases, the reporting and certifying of births and deaths, and all matters pertaining to public health . . .", was amended by the Act of July 11, 1923, so as to provide that osteopathic physicians and surgeons should act in such regard "the same as physicians of other schools" and so as to provide further that such reports "shall be accepted . . . by the officers, boards, bureaus or departments of the state . . . to whom the same are made, with the same force and effect as reports or certificates issued by physicians of other schools. . . ." These amendments neither amended nor purported to amend the mental health act in the slightest particular.

In the final analysis, the Supreme Court concluded, what the defendant urges us to do is to formulate legislative policy rather than interpret already expressed legislative intent. It is not within our province arbitrarily to fasten on the legislature a new nomenclature. Our duty is to interpret the presently germane statutes according to the usual and ordinary meaning of their plain and unmistakable words and terms. Accordingly, the Supreme Court reversed the decree of the trial court in favor of the defendant and remanded the case with instructions to grant the injunction requested. *Palmer v. O'Hara, Secretary of Welfare, et al, 58 A (2d) 574 (Pennsylvania, 1948).*

Workmen's Compensation Acts: Employee's Refusal to Undergo Spinal Puncture.—This was action to recover an award under the workmen's compensation act for injuries sustained during the course of the claimant's employment. From an adverse judgment, the claimant appealed to the Supreme Court of South Carolina.

The claimant received a back injury in compensable circumstances and was paid compensation for about six months. Some time during this period he was examined by a specialist to whom the employer had sent him and who reported in part: "I suspect that this man has a ruptured intervertebral disk. He should have a spinal myelogram performed in order definitely to establish or rule out this diagnosis. If a ruptured disk is demonstrated, then it should be removed surgically." The claimant refused to submit to the spinal puncture, and payments were therefore terminated pursuant to the section of the workmen's compensation act providing: "If the employee refuses to submit himself to or in any way obstructs such examination requested by and provided for by the employer, his right to compensation and his right to take or prosecute any proceedings under this article shall be suspended until such refusal or objection ceases, and no compensation shall at any time be payable for the period of compensation, unless in the opinion of the industrial commission the circumstances justify the refusal, or obstruction."

At the hearing before the Hearing Commissioner, medical testimony on behalf of the claimant was expressly invited but was not forthcoming. Only the claimant testified. He was entirely uneducated, unable to read and write and dependent on manual labor for support of himself and family. He said that he was afraid of the puncture and afraid "to be worked on in the spinal part anywhere at all"; further, that he knew of persons who had been disabled as the result of such, and a friend, he said, had died from a "spinal shot." The court of common pleas found that the claimant's refusal of the diagnostic treatment was not well founded and that the carrier was justified in discontinuing payment of compensation. On appeal to the Supreme Court, the claimant's counsel argued that the conclusion of the Commission (which ordered payments resumed) was one of fact which the court could not disturb if there was supporting evidence, and it was contended that the claimant's testimony of his information of other cases which resulted disastrously was some evidence to justify his refusal to submit to a spinal puncture, which was particularly conclusive in the absence of express medical testimony that the recommended procedure was not dangerous. The myelogram, said the Supreme Court, is commonly known as a spinal puncture, by means of which a specimen of the spinal fluid is withdrawn for examination. This, of course, is used for the purpose of diagnosis and is not surgery or treatment as those terms are ordinarily used. To a layman, the court continued, much of medical science is mystery, but not so a spinal puncture. It is common knowledge that it is not at all unusual. It is apparent from the record, the court continued, that the suspension of compensation payments to claimant really resulted from his unfortunate ignorance and misinformation, but the law cannot be molded to meet his standard; instead it must be made to fit the traditional average reasonably prudent man of ordinary courage. The Supreme Court was accordingly of the opinion that the claimant should have submitted to the spinal puncture for the purpose of diagnosing his true ailment, and the judgment of the court of common pleas requiring that payments of compensation be discontinued was therefore affirmed.—*Wardlaw v. J. G. Ridgeway Const. Co., 46 S. E. (2d) 662 (S. C., 1948).*

Compensation of Physicians: Sending Collection Letters to Patient's Employer.—The plaintiff sued for damages for an invasion of her right of privacy and for libel and, from a judgment for the defendants, appealed to the appellate court of Indiana.

The plaintiff had been a patient of the defendant physician and had received services valued at $65 over a space of time. This sum having remained unpaid for about five years, the account was placed in the hands of a collection agency. Subsequently the collection agency, on behalf of the physician, sent a series of letters to the plaintiff's employer advising him of the debt and asking his assistance in collecting it. The plaintiff contended that this action was both a libel and an invasion of her right of privacy. The defendants contended that the facts alleged were insufficient to sustain an action either for libel or for an invasion of any right of privacy.

As a complaint for damages resulting from libel the plaintiff's statement is clearly insufficient, said the court. The words complained of are not libelous *per se,* and there is no allegation of special damages. The general rule is expressed thus in 33 Am. Jur., Libel and Slander, section 60: "As respects a charge of failure to pay debts, without imputation of insolvency, it seems to be settled that a writing containing the mere statement that a person who is not a trader or merchant, or engaged in any vocation wherein credit is necessary for the proper and effectual conduct of his business, owes a debt and refuses to pay, or owes a debt which is long past due, is not libelous *per se* and does not render the author or publisher of such statement liable without proof of special damages."

Continuing, the court said that it seemed clear that the plaintiff really was not complaining of a libel but rather of an invasion of her right of privacy through the conduct of the defendants in giving unwarranted publicity to her failure to pay a debt and attempting thereby to coerce her into paying it. Whether or not her complaint is good on such a theory presents a more difficult question, said the court. If the plaintiff's complaint pleads a case for the invasion of her right of privacy, it lies solely in the fact that the defendants, in an effort to collect a bill, brought the matter to the attention of the plaintiff's employer through a series of letters in which the employer's aid was solicited and the facts and circumstances of the indebtedness were detailed. In the course of routing said letters to the employer's appropriate executive officer, they were read by numerous clerks or other office employees. It must be borne in mind, said the court, that an employer has a natural and proper interest in the facts relative to debts owed by his employees. He is subject to the expense and inconvenience of defending himself in garnishee proceedings wherein a percentage of his employees' wages may be taken to apply on such debts, and thus additional and burdensome bookkeeping entries may be imposed on him. He has the right to hire only those who pay their debts and may take a pardonable pride in the reputation of his employees in that respect. He is not in a category with the general public which cannot have any legitimate interest in a purely private matter between a creditor and a debtor. For these reasons, said the court, an employer has a right to know the status of the financial obligations of his employees, and, while we cannot say that a creditor owes an employer a duty in that regard, it is difficult to follow a course of reasoning that concludes that an employee's right of privacy has been invaded by giving his employer information which he has a right to have. In other words, an employee has no right of privacy, as against his employer, in the matter of the debts he owes and a creditor who gives such information to the employer, unaccompanied with slanderous, libelous, defamatory or coercive matter, incurs no liability in so doing. The fact that in the usual course of business the communication may pass through the hands of clerks or stenographers does not alter the rule. The situation is somewhat analogous to that of a privileged communication which does not lose its character through such process. Accordingly the judgment in favor of the defendant physician and the defendant collection agency was affirmed.—*Patton v. Jacobs, 78 N. E. (2d) 789 (Ind., 1948).*

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1936 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied with stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Procedure to Facilitate Intracapsular Forceps Extraction of Intumescent Cataracts. L. Daily Jr. and R. K. Daily. -p. 328.

Saline Injections in Retinal Attachment.—According to Grafton and Guyton reattachment of the retina was obtained in 69 per cent of eyes in which the retina looked flat at the close of operation. In contrast, reattachment was obtained in only 26 per cent of eyes in which the retina was appreciably elevated at the close of operation. During recent years at the Wilmer Institute saline solution has frequently been injected into the vitreous at the close of the diathermy operation in order to force subretinal fluid out of the eye and if possible reposit the retina against the choroid. The present study represents an evaluation of the possible beneficial effects of these saline injections. In a series of diathermy operations for retinal detachment, including 159 first operations and 40 second operations, saline solution was injected into the vitreous in most instances in which the retina remained elevated at the conclusion of diathermy application and scleral punctures. The percentage of reattachment in these eyes was as high as the percentage of reattachment in those eyes where saline injections were not necessary to cause flattening of the retina. The authors believe saline solution (or air) should be injected unless the retina flattens almost completely without the necessity of such a procedure.

Tumors of Carotid Body.—Donald and Crile observed 5 patients with tumors of the carotid body at the Cleveland Clinic. Irradiation has been almost universally unsuccessful against tumors of the carotid body. Surgical treatment is difficult because of inaccessibility of the tumor, which in many instances extends beneath the mandible to present in the pharynx or tonsillar fossa, and because of hemorrhage. The most satisfactory approach has been through a wide incision over the long axis of the tumor with careful sharp dissection along the cleavage plane separating the mass from the adherent large vessels. Ligation of the common carotid artery is not to be undertaken lightly; a high mortality results from such a procedure. Complications such as hemiplegia and aphasia are caused by cerebral ischemia. Damage to the jugular vein, the recurrent laryngeal nerve, hypoglossal nerve, facial nerve or sympathetic trunks has occurred in 24 per cent of 148 patients who underwent operation. It was necessary to ligate the common carotid artery in approximately 50 per cent of the patients, producing a mortality rate of 30 per cent. About 50 per cent of the survivors suffered permanent cerebral damage. Periodic compression of the artery for several weeks prior to operation might feasibly stimulate collateral cerebral circulation and decrease the complications resulting from ligation. The carotid artery should not be sacrificed unless its ligation is necessitated by uncontrollable hemorrhage. If patience and care are used, most tumors of the carotid body can be removed without damaging the carotid artery. In 1 of their cases the tumor of the carotid body metastasized to the bones.

Treatment of Varicose Ulcer.—Varicose ulcer is most often located in the region of the medial malleolus. It is in this region that the hydrostatic pressure and stagnation of fluid is most severe when the great saphenous vein is varicosed. In addition, the exposed ankle is prone to minor traumas which frequently initiate the ulcer. When large varicose veins with demonstrable reverse flow are present, it has been Cooper's practice to operate early rather than late. This frequently shortens the period of pain and disability. When dermatitis and eczema are present, elevation and the application of wet dressings usually clear up the condition. "Domeboro tablets" offer a convenient method of preparing Burow's solution. One crushed tablet dissolved in 1 pint (473 cc.) of water makes a stable, buffered and nonirritating Burow's solution of 1:20 strength. When infection or epidermophytosis is present as a complicating factor, wet dressings of potassium permanganate solution 1:5,000 may prove effective in preparing the area for subsequent "daxalan" and Dome boot therapy. "Daxalan" is a rigidly standardized, uniformly colored, aged crude coal tar product of the formula: crude coal tar 2.88; zinc oxide 5.37; starch 53.75 and sufficient petrolatum to make one hundred parts. The Dome paste boot is a modified Unna's paste boot. When the skin has been cleansed, a thick application of "daxalan" ointment is made directly to the ulcer and the surrounding skin. Talcum powder is then sprinkled on the surface of the ointment application and a smooth, evenly applied Dome boot is then placed on the limb from the toes to the knee. The patient is usually ambulant after the boot application and is encouraged to remain so. The boot is cut after one week, the ulcer and surrounding skin cleansed and a second application of "daxalan" ointment, talcum powder and Dome boot is made. The same routine is repeated until the ulcer is firmly healed. One hundred and forty-seven subjects with chronic leg ulcers were treated by the "daxalan"-Dome boot technic. The maximum period required to effect a cure was ten weeks and the minimum, two weeks. Sensitivity or allergy to "daxalan" was encountered in only 2 patients. A patch test should be done on each new patient.

Para-Aminobenzoic Acid in Murine Typhus.—Fuller reports observations on the efficacy of para-aminobenzoic acid in 11 patients over 30 years of age, in whom diagnosis of typhus was proved. The effective drug level in murine typhus is above 10 mg. per hundred cubic centimeters of blood. The authors believe that they have been far too cautious in administering the drug, for not once was a blood level of 10 mg. reached. In a patient treated more recently an initial dose of 8 Gm. and then 4 Gm. every two hours day and night thereafter were given, and drug levels of 11 and 14 mg. were obtained. This is what is now believed to be the effective range in endemic typhus. The patients received only half or a little more than half of this amount. Para-aminobenzoic acid should be given with sodium bicarbonate or other alkali to keep the urine alkaline. Administration of the drug should be discontinued if crystallization occurs. The drug should be given for forty-eight hours after the temperature has reached the normal. Sulfonamide drugs should not be given during the course of treatment with para-aminobenzoic acid. The effect of sulfonamide compounds is inhibited in vitro by even small doses of para-aminobenzoic acid. If complications arise that require the use of other drugs, penicillin or streptomycin should be used. The authors gained the impression that para-aminobenzoic acid shortens the duration of typhus.

Treatment of Asphyxia by Firemen.—Spurgeon says that for many years fire departments have had some sort of apparatus to resuscitate persons who have drowned or who have become asphyxiated with gas or who have ceased to breathe for some other reason. In almost all cases firemen arrive on the scene before the physician, and often long enough before to make the difference between success and failure. The apparatus called inhalator delivers oxygen and carbon dioxide under moderate controlled pressure and may be used in conjunction with artificial respiration by the manual method. The respirator delivers carbon dioxide and oxygen under pressure. This apparatus can be regulated to produce inflation of the lungs and then suction, to remove the air from the lungs. This apparatus performs artificial respiration mechanically. The author is of the opinion that fire departments should be encouraged to respond to cases of asphyxia and that physicians should give the department cooperation, but unless a physician also responds to the call and cooperates with the firemen a patient will occasionally be lost who could have been saved. In certain cases more than artificial respiration is required if a life is to be saved. It is important to determine the causes of the cessation of respiration, but it is unwise to send a patient to the hospital whose respiration has ceased. Artificial respiration should be given immediately.

Purified Rickettsial Suspensions.—Castaneda points out that the cultivation of typhus rickettsiae in the lungs of animals is a convenient method for obtaining antigenic material in amounts sufficient for human immunization. Separation of the considerable amount of impurities from the organisms has been difficult. The author describes a new method for the purification and concentration of typhus rickettsiae cultivated by the "lung method." The material thus obtained may be used for various serologic tests such as agglutination, complement fixation and opsonization. A suitable dilution of the stock suspensions may be used for the preparation of monovalent and bivalent vaccines which have been widely tested in the immunization of human beings. For emergency work an oil protected bivalent vaccine to be administered in a single dose is now being tested. The highly purified rickettsial suspensions have been successfully used to detect allergic reactions in typhus-immune persons, with results which have indicated their value in epidemiologic surveys.

Rapid Treatment of Early Syphilis.—This report by Heller and his associates is the ninth in a continuing series of progress reports evaluating the effectiveness of various forms of rapid therapy for early syphilis. Treatment and follow-up data have been furnished by fifty state and locally sponsored rapid treatment centers. This report is limited to schedules utilizing penicillin, either alone or combined with oxophenarsine hydrochloride, with oxophenarsine and a bismuth compound or with fever therapy. The schedule with the lowest cumulative retreatment rate (4.3 per cent) and the highest rate of seronegativity (80.8 per cent) is the schedule employing 3,400,000 units of aqueous penicillin given in injections of 40,000 units at two hour intervals. The relative safety of schedules that use penicillin alone as compared with schedules that combine oxophenarsine hydrochloride with penicillin is shown by the following facts. There were no fatalities when penicillin was used without oxophenarsine. The severe reaction rate in 1,000 treated patients was only 6.3 for aqueous penicillin used alone and 3.1 for penicillin in oil and beeswax. A total of 16 treatment deaths occurred when oxophenarsine hydrochloride was used with penicillin; the rate was 1 death for every 5,900 patients treated with oxophenarsine combined with aqueous penicillin and 1 death for every 30,300 patients treated with oxophenarsine combined with penicillin in oil-beeswax. Hemorrhagic encephalitis was the principal cause of death in methods utilizing oxophenarsine combined with penicillin.

Vagotomy in Ulcerative Colitis and Regional Enteritis.—Dennis and his associates performed vagotomy in 22 patients with idiopathic ulcerative colitis and in 1 case of functional diarrhea. One patient died of cardiac complications without completion of the vagotomy. Two patients are worse, 3 are unchanged, 14 have improved and 3 have not been operated on long enough for evaluation. Two of the excellent results occurred in patients who also had regional enteritis. Patients with longstanding disease and those who had much fibrosis of the bowel wall seem to have done less well than those in the acute phase and those having good bowel elasticity. It is still difficult to say which patients will be unchanged or injured by division of the vagus nerves. The authors emphasize that vagotomy should not be employed promiscuously, but only where serious study and evaluation of the method are the aims.

Anatomic Aspects of Gastric Neurectomy.—Bradley reports on 100 dissections made at necropsy. The gastric nerves arose from the esophageal plexus at about the level of the bifurcation of the trachea. The right and left gastric nerves coursed caudad and terminated on the stomach. There were certain qualitative variations that permitted classification of the dissections into four groups. The first group of 64 dissections was characterized by the fact that all branches between the gastric nerves and from more remote sites joined to form common trunks on the right and left sides of the esophagus somewhere between the superior aspect of the diaphragm at the esophageal hiatus and 6 cm. above the diaphragm. In the second group of 7 dissections there were so many intercommunications between the main trunks of the gastric nerves that a plexus was formed on a major portion of the anterior surface of the esophagus. The third group of 21 dissections was characterized by the fact that the long discrete trunks had neither additions of fibers nor intercommunications below a point 6 cm. above the diaphragm. In the fourth group of 8 dissections no consistent or uniform course or pattern was found. In some instances well formed trunks were evident from which, somewhere near the diaphragm, a well-defined branch left a main trunk, coursed laterally in the thorax and became lost before leaving the thorax. Another variation was that of a failure of the numerous branches of the esophageal plexus to form a common trunk. In this group were found nerves with a course and distribution which might cause difficulty for the surgeon who attempted to section the gastric nerves. In 92 per cent of the dissections distinct right and left gastric nerves could be identified at the esophageal hiatus. In 8 per cent the arrangement of one or both gastric nerves was abnormal and irregular. Identification of such nerves in the performance of gastric neurectomy would require thoracic approach.

Pulmonary Embolism After Venous Sclerosing Therapy.—Smith and Johnson say that in the period 1927 through June 30, 1947, 11,700 patients were given sclerosing treatment for varicose veins at the Mayo Clinic. In 17 of these pulmonary embolism developed, an incidence of about 1.4 per thousand. There was only 1 death from pulmonary embolism. Anticoagulant therapy has proved adequate when venous clotting appears likely or nonfatal pulmonary embolism occurs, and occasionally operation is resorted to in addition. A thorough preliminary history and examination are essential in cases in which sclerosing treatment is planned.

Capillary Fragility and Diabetic Retinitis.—Rodriguez and Root report measurements on capillary fragility of 156 diabetic patients. They used the petechial index of Gothlin. Forty per cent of 100 unselected diabetic patients showed an increased capillary fragility. This abnormality was found in practically all patients with diabetic retinitis, whether or not hypertension was present. In 11 cases hypertension was present with increased capillary fragility, but no retinal damage was observed. In 56 selected cases with retinitis no patients showed a normal petechial index. The petechial index was increased in 47 and borderline in 9. The incidence of increased capillary fragility was related to the duration of the diabetes more clearly than to the age of the patient; 41.4 per cent of 82 patients with retinitis were under 40 years of age, and increased capillary fragility was observed as early as the age of 21 years, but with long duration of diabetes. Rutin was administered to 70 patients with retinitis and increased capillary fragility. The initial dose was 20 mg. three times a day, and this was increased to 40 or 60 mg. three times a day in 20 cases. (A dosage of 300 to 400 mg. daily may be used.) Increased capillary fragility can be brought to normal with the use of rutin in sufficient dosage, although no patient with retinitis was improved. Increased capillary fragility occurs in diabetic patients as an early evidence of generalized arterial disease and is closely correlated with the development of retinitis and later nephritis.

Multiple Lesions in Primary Syphilis.—Kuhl and Boggs say that one of the most popular misconceptions of the medical profession is that primary lesion of syphilis is always single. They found at the Kanawha Valley Medical Center that 38.5 per cent of 652 patients with diagnosis of primary syphilis had multiple lesions. In 190 seronegative dark-field-positive untreated cases of primary syphilis 43.2 per cent of patients had multiple lesions. Persons with multiple primary lesions tend to come for treatment earlier than those with single lesions. There is no recognized tendency for one sex to have multiple primary lesions more frequently than the other. Extragenital primary lesions are more frequently single than genital primary lesions.

Serum Albumin in Cerebral Edema.—According to Gates and Craig, cerebral edema can seriously interfere with the recovery of a patient who may have undergone a technically successful operation for an intracranial tumor. This report is based on 31 cases of intracranial tumor or injury of the head in which a 25 per cent solution of dry serum albumin was administered intravenously to relieve cerebral edema. It was possible to evaluate the results of this treatment in 20 cases. Improvement occurred immediately after the administration of the serum albumin in 8 of the 20 patients. Four patients were improved, although the improvement did not occur immediately. The serum albumin did not produce untoward reactions. Administration of serum albumin should be considered after surgical operations for intracranial tumor in which cerebral edema is suspected and to prevent cerebral edema after injury of the head.

Pulmonary Resection for Abscess of Lung.—Glover and Clagett say that during the ten year period from January 1937 through December 1946 pulmonary resection has been performed in 37 cases of pulmonary abscess at the Mayo Clinic. These cases were taken from a large number in which resection was performed for pulmonary suppuration. They represent only those in which the diagnosis from the onset was that of pulmonary abscess. The patients were well before the present illness. In 20 cases abscess occurred during the course of an infection of the respiratory tract, usually stated as being pneumonia. In 11 cases the abscess followed the administration of an inhalation anesthetic agent, most frequently in operations about the mouth, such as tonsillectomy, extraction of teeth and drainage of sinuses. In 5 cases a foreign body was found in the resected specimen. In 1 case the abscess followed an injury to the thoracic wall, in which a segment of rib had pierced the lung, causing hemoptysis, infection and cavitation but not hemothorax. . The average elapse time from diagnosis to resection was eighteen months, the extreme being eleven years. There were 2 cases of partial resection, 16 of lobectomy, 3 of bilobectomy and 16 of pneumonectomy. In the 21 cases in which a conservative resection (lobectomy or less) could be performed, there was 1 death. In the remaining 20 cases the results were good. In contrast, of the 16 cases in which total pneumonectomy was performed, a good result was obtained in only 7, and in 3 of these it was delayed considerably by complications. There were 6 deaths attributable to operation and 3 late deaths resulting from abscess of the brain. The authors believe that if the optimal time for surgical intervention is recognized and there is quick action, the problem of chronic pulmonary abscess will be eliminated. Until such a time pulmonary resection is the treatment of choice for suppuration of long standing. Bronchographic follow-up of patients treated by open drainage reveals that a significant number are left with residual parenchymal and bronchiectatic changes. Pulmonary resection should therefore take preference over open drainage.

Sulfadiazine in Hyperthyroidism.—Mulholland and his co-workers say that in September 1941, as a measure intended to prevent infection, sulfonamide therapy was instituted following thyroidectomy whenever the temperature rose to 101 F. Sulfonamide therapy was so satisfactory in controlling the temperature and associated infection that it was decided to give the drug before operation in an effort to prevent postoperative infection. Each patient received 8 Gm. of sulfadiazine by mouth in divided doses in the twenty-four hour period before operation The sulfadiazine was continued after operation, 4 Gm. daily, for two to four days. It seemed possible on the basis of reports that by the use of sulfadiazine dual effects were being obtained, i. e., antithyroid and anti-infective. This method of therapy has now been used on a total of 75 patients. In addition to the usual preoperative therapy with strong iodine solution U. S. P., most of the patients received 8 Gm. of sulfadiazine in the twenty-four hours before operation. The postoperative course in these patients was not attended by any severe reaction and the temperature and pulse rate were well controlled. In patients not receiving the sulfonamide compound before operation, the drug was given after operation when the signs suggestive of thyroid crisis occurred; i. e., rapid heart rate, restlessness and a rise in temperature to 101 F. In every instance the temperature and heart rate decreased and the patient's condition improved. The effect of the sulfadiazine occurred within twelve hours of its administration. In this group of patients treated with sulfadiazine and strong iodine solution there were no deaths, whereas in a similar group of 75 patients receiving strong iodine solution and operated on there were 4 deaths.

Acute Pneumocholecystitis.—Heifetz and Senturia define pneumocholecystitis as an acute infection of the gallbladder characterized by the production of gas within the lumen of the gallbladder. The term acute pneumocholecystitis seems preferable to pyopneumocholecystitis, since there is no certainty that in all cases there is pus in association with gas. The name emphysematous cholecystitis also lacks inclusiveness, since the emphysematous pericholecystic infiltration of gas is not invariably present. Besides the Clostridium perfringens, other gas-forming organisms may exist in the bile tract. For the most part they seem to exist as harmless saprophytic inhabitants. Examination of the literature of the last forty-five years has uncovered only 8 bona fide cases of acute pneumocholecystitis. These 8 cases are reviewed and 2 cases diagnosed preoperatively are added. Although one would suppose that acute pneumocholecystitis is a fulminating and invariably fatal disease, this was not true. The picture is one of persistent acute pain in the upper part of the abdomen, usually after previous attacks of pain associated with the gallbladder. Tenderness and rigidity are prominent features, and when the rigidity permits, the gallbladder and occasionally the liver edge can be felt. This picture is not unlike that of other cases of acute cholecystitis or empyema of the gallbladder. There is, however, a tendency for the inflammatory signs to persist, and failure of the attack to resolve would lead to gangrene and perforation. The presence of gas in an acutely inflamed gallbladder is an incidental finding, although its presence makes for additional problems. Surgical therapy alone is effective. Polyvalent gas antiserum, sulfonamide drugs, penicillin and roentgen therapy are of questionable value. Routine scout roentgenograms of the gallbladder area in clinical cholecystic disease will aid in the recognition of this distinctive form of acute cholecystitis.

*Effect of Pregnancy on Translucence of Mammary Gland. L. Halberstaedter. -p. 65.

Translucence of Mammary Gland and Pregnancy.—In examining several hundred women with suspicious lumps in the breast by means of Cutler's transillumination method, Halberstaedter found that the method was a helpful supplement to the routine physical technic of the examination of the breast. It is especially useful in the early stages of malignant tumors. He found that it was impossible to use this method during pregnancy, since the breasts lost their translucence and became gradually more opaque. He endeavored to find out at what stage after conception translucency of the breast first begins to diminish and how far this sign can be used as proof of pregnancy and as a method of differentiating between certain pathologic processes and pregnancy. He observed that during the first six weeks of pregnancy the breasts are still clearly translucent. In the period between six to ten weeks the translucency begins to diminish. After ten weeks the fading of the translucency is easier to determine, and after twelve weeks the breasts are with only a few exceptions opaque. The author concludes that a decrease of translucency of the breast may indicate pregnancy. This sign can be useful as a quick and easy method of differentiating between pregnancy and other processes, but only if it is clearly positive.

Tuberculous Cervical Adenitis.—Bailey reviews the rise of surgical treatment in the period between 1885 and 1908 and its subsequent fall and replacement by heliotherapy and roentgen treatment. During the last twenty years treatment with roentgen rays has declined in favor, since it is not without serious disadvantages. It converts the skin into leather and produces underlying fibrosis. Occasionally roentgenologic burns are encountered. On rare occasions malignant disease follows irradiation. Tonsils, adenoids and carious teeth are the chief portals of entry for the tubercle bacillus into the cervical lymphatic system. Bailey describes the four progressive stages of tuberculosis in the cervical lymphatic system and discusses treatment by aspiration, giving particular attention to the causes of the high proportion of bad results following aspiration. Curettage is not divorced from the disaster of disseminating tuberculosis. The procedure should be abandoned. Surgeons familiar with thyroid surgery and many progressive otorhinolaryngologists are especially adaptable to this work. Any surgeon with a good knowledge of the anatomy of the neck can quickly become adept, provided he has the time and patience to undertake the dissections. Diseased tonsils and especially adenoids should be removed by an otorhinolaryngologist or a surgeon especially trained in the removal of adenoids. Provision should be made for adequate convalescence up to two or three months in an institution with a nurse especially trained in the correct method of dressing open wounds.

Arthritis and Working Ability. C.B. Heald. -p. 17.

*Metal Fume Fever. J.W.E. Raine. -p. 24.

Metal Fume Fever.—According to Raine, metal fume fever is applied to a number of conditions and embraces such entities as brass founders' ague, smelter shakes, zinc chills, brass chills and founders' fever. It can be caused by several different substances, one of which is zinc oxide. The author presents the history of an electric welder, aged 37, who reported on Sept. 3, 1947 that during the previous two days he had been engaged in welding galvanized iron beds on a ship. He inhaled a large quantity of fumes. On the morning of September 2 he had a headache, nausea, a colicky upper abdominal pain and a severe cough with slight hemoptysis. On examination, shortness of breath was observed and a roentgenogram of the chest revealed widespread abnormal shadows in the left midzone and a similar condition in the upper lobe of the right lung. During the next ten days the temperature and pulse rate gradually fell to normal. The patient was discharged on September 19, feeling well and having a normal chest on roentgen examination.

Folic Acid in Nutritional Anemia. Cowan asserts that severe anemia is responsible for much ill health in Malaya and that the death rate is high. The causes include malaria, intestinal infestation with worms, malnutrition and chronic infection. Of 142 cases investigated in detail, in 24 the red blood cell count was less than 1,000,000. Analysis of these 24 cases showed that nutritional macrocytic anemia accounted for 9, dimorphic anemia for 14, and iron-deficiency anemia for 1 only. A nutritional factor apart from iron was thus concerned in 23 cases. In 5 of these 23 cases treatment was with oral synthetic folic acid. The response to treatment was satisfactory in all instances, and dramatic in 2 cases of dimorphic anemia. The author concludes that the drug has life-saving potentialities when used for moribund patients with dimorphic anemia--an attribute of prime importance in Malaya, where nutritional anemia is responsible for many deaths. The value of the drug is further enhanced by the fact that red cell concentrates for transfusion are virtually unobtainable in Malaya.

Gastric Lavage and Laryngeal Swab in Detection of Tubercle Bacilli.—Hounslow and Usher describe the technic of cultural examination of gastric washings and of laryngeal swabs. A comparison is made between the two methods. Results of examining 193 patients by 193 lavages and 329 swabs (taken on the same or consecutive days), are presented, together with a series of 23 patients whose gastric washings were inoculated on three Löwenstein slopes. The results seem to favor three laryngeal swabs. The authors stress that this type of examination not only is less unpleasant to the patient than gastric lavage but involves less time and skill on the part of the nursing and laboratory staff. The results of three consecutive laryngeal swabs are as good as, and probably better than, a single gastric lavage. Laryngeal swab examination is a reliable, practicable, simple method of examining pulmonary secretions for tubercle bacilli; it is suitable for routine use both in hospitals and outpatient clinics, for diagnosis and in the management of pulmonary tuberculosis.

•Case of Adrenal Pheochromocytoma Clinically Diagnosed and Cured by Operation. N. Alwall and H. B. Wulff. -p. 337.
Splenic Tissue in Scrotum. E. Sartor. -p. 388.

Adrenal Medullectomy in Disorders of Vascular System.—Of the 2 cases reported by Boggild, the first concerned a man with severe spontaneous gangrene in all extremities; the second concerned a woman, aged 18, who had severe frostbite with chronic vascular changes (blue legs). In both cases sympathetic ganglionectomy failed to produce satisfactory results and a bilateral adrenal medullectomy was performed. An oblique incision is made under the seventh rib, which is mobilized by subperiosteal resection of 1 cm. of the bone close to the processus transversus. It is then easy to enter and identify the upper pole of the kidney. The operator should work along this until the nearest edge of the adrenal is found. An incision is made and a blunt instrument inserted. The adrenal gland is transformed into a cavity which is then excochleated with a small uterine curet. During this procedure a good deal of the cortex will be removed in addition to the medulla, but enough can be left to preserve life. The surgical operation produced favorable results in 2 patients.

Seminal Vesiculitis.—Geijerstam reports 4 cases of seminal vesiculitis, 3 of which simulated acute appendicitis. In 2 cases appendectomy was performed. The fourth case had been diagnosed as renal calculus. The author points out that four main sites of referred pain of seminal vesiculitis exist: the lower abdomen, the course of the ureters, the course of the vas and the epididymis, and the sacral region. As symptoms from the genitourinary system are often lacking, the correct diagnosis may be difficult, especially when the abdominal referred pain is predominatingly on the right side. Many surgeons fail to include seminal vesiculitis in the differential diagnosis when acute abdominal symptoms are present; this may explain why seminal vesiculitis is so frequently mistaken for appendicitis or ureteral colic. The author stresses the importance of a careful sexual and urologic history. Although other observers regard gonorrhea as the most frequent cause, the author found no evidence of this disease in his 4 cases. The diagnosis of seminal vesiculitis is corroborated by rectal examination, which should be made with the patient erect or in knee-elbow position. If the vesiculitis is of infectious origin, sulfonamide drugs and penicillin should be given. Barbiturates may be administered if excessive sexual irritability has to be counteracted. Hot sitz baths, hot rectal irrigations and heat to the perineum often give comfort and diminish the pain.

Adrenal Pheochromocytoma.—Alwall and Wulff report the case of a man, aged 43, who was completely invalided for four years on account of attacks of pallor, perspiration, trembling and, during the last year, spells and symptoms similar to those in ulcer cases. The clinical diagnosis of pheochromocytoma was verified by roentgen examination. A large adrenal tumor on the right side was found. Reexamination of pictures taken four years previously revealed an adrenal tumor. After the tumor was successfully removed surgically the symptoms disappeared completely.

Clinical Pictures Masking Bronchopulmonary Cancer. A. P. Noef. -p. 123.

•Importance of Calcium in Treatment of Delirium Tremens. Z. Klimo. -p. 135.

Calcium in Treatment of Delirium Tremens.—Klimo gained the impression that support of the circulation is of greatest importance in the treatment of delirium tremens, since death in delirium seems to be largely a result of failure of circulation. It has been proved in experiments that the calcium content of the blood is of vital importance for cardiac function. Furthermore, calcium is valuable in pneumonia that may complicate delirium and has a favorable effect on the nervous system. These considerations induced the author to resort to the parenteral administration of calcium in 29 patients with delirium tremens. The patients were given daily from 40 to 60 cc. of a calcium preparation intravenously and intramuscularly. For the intravenous administration a 20 per cent calcium preparation was used and for intramuscular administration a 10 per cent solution. Calcium therapy was combined with the administration of vitamin B_1 and ascorbic acid and with small doses of cardiac stimulants. In most patients improvement became evident on the second day of treatment. The condition of the circulation and the hypovitaminosis deserve primary attention in delirium tremens. Soporific drugs are contraindicated.

•Primary Cancer of Gallbladder and of Biliary Ducts. A. Urzúa and M. Matus. -p. 17.

Simple Orthopedic Apparatus in Treatment of Poliomyelitis Sequels. E. Diaz Borden. -p. 25.

Primary Cancer of Gallbladder and of Bile Ducts.—Urzúa and Matus report 22 cases of cancer of the gallbladder and 2 cases of cancer of the bile ducts. All patients except 1 were women. Most patients were between the ages of 60 and 70. Cancer and lithiasis coexisted in 17 cases. The early symptoms are those of gallbladder disease. The advanced period is manifested by aggravation of the gallbladder symptoms, appearance of a palpable tumor and rapidly progressive emaciation. In this stage no treatment is available. The life expectancy in this stage is about nine to ten months. Early surgical intervention in all cases with clinical symptoms of biliary lithiasis as prevention of cancer is advisable.

•Dermatitis Provoked by Mineral Oils. A. Tzanck, E. Sidi and S. Dobkevitch. -p. 343.

Significance of Medical Bronchoscopy in Hospital Service For Adults. A. Breton and J. Mereau. -p. 347.

Relationship of Narcoanalysis or Psychotherapy Under Anesthesia to Psychoanalysis. J. A. Chavany, M. Bouvet and D. Hagenmuller. -p. 353.

Dermatitis Due to Mineral Oil.—According to Tzanck and his co-workers, the use of mineral oil (liquid petrolatum) for industrial purposes, for therapeutics in dermatology and for cosmetic purposes has increased considerably. Cutaneous manifestations differing in their clinical aspect and in their significance may result from each of these different types of use. A group of cases of acneform dermatitis is described in which manifestations are of a collective character occasionally simulating an epidemic. The impurity of the oils used in the manufacture of brilliantine, for the therapeutic creams on an anthracene basis or for lubricating purposes, may be responsible for the occurrence of oil pustules. These cutaneous lesions may be prevented by the use of purified or aseptic oils and by washing with soap and by changing clothing. The second group is one of eczematous dermatitis with individual manifestations due to sensitization. The latter may be aggravated by contact with the sensitizing substance combined with repeated microtrauma of occupational origin. The manifestations require change of occupation. Precautionary measures are of no avail, and recovery results only from avoidance of contact. Four cases of Riehl's melanosis in workmen and 2 cases in women after the use of beauty creams are reported. Ulcers, precancerous keratosis and cancer of the skin belong to another group of disorders which are caused by petroleum or tar.

Book Notices

What Comes of Training Women for War. By Dorothy Schaffter, for the Commission on Implications of Armed Services Educational Programs. Cloth. Price, $3. Pp. 223, with 8 illustrations. American Council on Education, 744 Jackson Place, Washington 6, D. C., 1948

This volume will be source material for all time on the facts of the women's branches of the Army, the Navy, the Air Forces, the Marine Corps and the Coast Guard. This book contains a concise statement of how many women served, how they were trained and their response to military life.

The wartime women's military services were the Women's Army Corps (WAC), the Women's Reserve of the Naval Reserve (Women Accepted for Voluntary Emergency Service, abbreviated as WAVES), the Women's Reserve of the Coast Guard Reserve (SPAR), the Marine Corps Women's Reserve (MCWR), the Army Nurse Corps, and the Navy Nurse Corps.

The Women Airforces Service Pilots (WASP) and the Cadet Nurse Corps of the United States Public Health Service should not, strictly speaking, be included, because these two services were not militarized. However, the WASP was like the women's military services in all other respects, and the work of the Cadet Nurse Corps was so closely related to that of the Army and Navy Nurse Corps that separation for purposes of description would have presented an inaccurate picture, and after consideration it seemed proper to include them.

This well organized book is divided into three parts and contains 11 chapters. Illustrations and tables enhance the value of the volume, which attempts to present a case from the point of view of services and of those who served. It points out that there can be no question but that the experiences of approximately one third of a million American women in the military services during World War II will have profound, long range effects on the position of women in America. Therefore, in these days of tremendous events, a thorough study of this volume is recommended for all who are concerned with planning for the future of our nation.

Members of the medical and nursing professions will be particularly interested in Part Three, entitled "Women in Medical, Nursing and Related Services." The author points out that American women have served as nurses to care for our wounded in every war since the Revolution, but that they first became a definite component of the Army when the Army Nurse Corps was created by Congress in 1901. Since the establishment of the Corps more than 100,000 nurses have been members.

This volume was not planned to glamorize the services. The opinions and assertions are private ones of the author and according to the foreword are not to be construed as official or as reflecting the views of the War Department or the Navy Department, or the military or naval services at large.

The Challenge of Parenthood. By Rudolf Dreikurs, M.D., Professor of Psychiatry, Chicago Medical School, Chicago. Cloth. Price, $3.50. Pp. 334. Duell, Sloan & Pearce, Inc., 270 Madison Ave., New York 16, 1948.

This book by a well known psychiatrist of the Adler school should be read by parents and by pediatricians as well. The book is one of the most sensible and practical of the numerous publications in this field. It is not so much a cold scientific analysis of the various abnormalities of behavior as an expression of warm understanding of the problems of childhood.

The book is divided into three sections. The first is a discussion of the psychologic background, describing the difficulties of the parents, their love, anxiety and often sense of inferiority, while the child struggles for superiority in the face of hardships of environment, and often neglect. In the second section the writer discusses the methods of maintaining the mental health of the child, such as keeping an orderly household, avoiding conflict and offering encouragement. He warns against the various mistakes, of which there are many: "spoiling," "lovelessness," "anxiety," "nagging," and many more. Then he elaborates specific situations such as *nursing, weaning and toilet training* and the innumerable questions that develop between infancy and adolescence. The last section is devoted to the difficult child. The author emphasizes the importance of understanding the underlying processes leading to the difficulty. Many of the child's reactions are based on his desire to attract attention. He may employ an active and aggressive technic but often accomplishes his end by a more subtle and passive approach. Coincidental with this drive may be the feeling of inadequacy, desire for revenge and striving for power.

The book ends with a brief description of the work of the Chicago Individual Psychology Association, of which the author is the medical director.

The only criticism that one might make is that the book, like most of those in this field, devotes itself chiefly to the child. Not so much consideration is given to the bewildered parents. However, if parents really understand the child their own troubles would diminish.

It is impossible to comment specifically on the countless valuable suggestions offered by the author. Suffice it to say that the author's main theme is, "Leave the child alone." In this respect the book should have the hearty endorsement of all pediatricians. That has been their theme for years. In fact, in its plea for sympathy for the child and for understanding, the book expresses the very spirit of pediatrics.

Health of Arc Welders in Steel Ship Construction: A Survey Made in Cooperation with United States Maritime Commission and United States Navy. By Waldemar C. Dreessen, Senior Surgeon, United States Public Health Service, and others. *From Industrial Hygiene Division, Bureau of State Services.* Prepared by direction of the Surgeon General. Public Health Bulletin No. 298, Federal Security Agency, United States Public Health Service. Paper. Price, 55 cents. Pp. 200, with 31 illustrations. Supt. of Doc., Government Printing Office, Washington 25, D. C., 1947.

This bulletin presents the results of investigations concerning the health of shipyard workers conducted during 1944 in seven shipyards located on the Atlantic, the Gulf and the Pacific coasts. The study was conducted cooperatively by the United States Public Health Service, the United States Maritime Commission and the United States Navy Department. The immediate reason for the undertaking was the increasing number of complaints of respiratory symptoms from shipyard workers.

The project included both environmental and medical surveys. Analyses were made of the fumes and gases contaminating the air of work places. Approximately 1,767 samples for iron and total fume were taken, 278 samples for zinc, 25 for lead and 2,019 for the oxides of nitrogen. In general, the concentrations of welding fume and gas recorded were relatively low. Some type of ventilation was available at all yards studied. Although the ventilation was of varying effectiveness, extreme degrees of atmospheric contamination were infrequent.

During the medical survey, 4,650 workers were examined. Approximately 1 out of every 4 persons was a nonwelder, the medical findings of this group serving to control the clinical data observed for welders.

Relatively few significant clinical symptoms which might be ascribed to occupational exposure were found. Among these were a respiratory symptom complex, arc welder's siderosis, cardiovascular hypotonia of slight degree, and rather characteristic occupational stigmas of certain arc welders, resulting from burns of hot slag or molten metal. Detailed blood studies failed to demonstrate any marked blood dyscrasias among welders. Gastrointestinal complaints were infrequent and there was no evidence found that welding fumes, under the existing conditions, predisposed to pulmonary tuberculosis. In general, the clinical findings were minimal.

The symptom complex involving the upper respiratory tract noted occurred slightly more frequently among welders than nonwelders: The clinical picture included pharyngitis, rhinitis, sinusitis and sometimes tracheobronchitis. These were ordinarily mild and nondisabling and undifferentiated in most respects from conditions of the upper respiratory tract induced by allergic or other irritant toxic agents or by infections.

The conclusion states that the great variation in the nature of the welder's work precludes reasonable estimates of weighted fume exposures, but safety and ventilating practices in the shipyards surveyed seem to have aided materially in holding occupational diseases at low levels of significance.

Junior Speaks Up. By Irving R. Abrams, B.S., M.D., Associate Attending Physician, Cook County Children's Hospital, Chicago. Cloth. Price, $2.50. Pp. 164. The Macmillan Company, 60 Fifth Ave., New York 11, 1948.

This book is authentic and useful as far as the information contained in it is concerned, provided that the reader is willing to put up with the annoyance of being talked down to and the excessive wordiness involved in the device adopted of trying to make a motion picture scenario out of advice about care of the infant. The result is neither an amusing style, as is apparently intended if one may judge from the comment on the jacket, nor a practical handbook of advice to young parents.

The characters are Mr. and Mrs. Worrimore (the parents), Dr. Bodybuilder, Junior (the real object of the book) and, for some reason that this reviewer is unable to fathom, an additional character in the "person" of Junior's shadow, who acts as a sort of interlocutor to Junior's Mr. Bones. The result is a lengthy, stilted, forced and definitely not funny production which is longer than it needs to be because the information is buried in so much extraneous matter. The parents appear more stupid than seems necessary, and many of Junior's conversations with Shadow are far too adult to be convincing. It is too bad that the forced effort to be humorous has spoiled what would otherwise have been a useful contribution to health education for young parents. The frequent references by Dr. Bodybuilder to the fact that the answers to questions by young parents are all found in his book "How to Raise Good Babies" is wearisome and in bad taste.

The Brain of the Tiger Salamander, Ambystoma tigrinum. By C. Judson Herrick. Cloth. Price, $5. Pp. 409, with 113 illustrations. University of Chicago Press, 5750 Ellis Ave., Chicago 37, 1948.

This book by the dean of American neuroanatomists contains much more than the title indicates. Its first, more general part, gives an over-all view of the brain of this amphibian, and discusses the physiologic and morphologic implications. It is well suited to the nonspecialist. Indeed, it is one of the most brilliant and lucid introductions to comparative neurology ever written. The basic plan of the vertebrate brain and how it works (chapter VI) and the changes which the different parts of the brain underwent during phylogenesis and which culminated in the development of the cerebral cortex (chapter VII) are described succinctly and clearly, and the value of morphologic studies for a broader understanding of man is discussed (chapter VIII).

The second part contains a detailed analysis of the fiber tracts and cell masses in the brain. This documentary material will be appreciated by the experienced worker in the field of neuroanatomy. Apart from the ordinary methods, silver preparations, including impregnations after Golgi, have been used.

There is a bibliography of ten pages which includes a list of the author's previous papers. The figures, all pertaining to the brain of the tiger salamander, are mostly line drawings; most of them are new. The book should be widely read, not only by specialists!

Child Care Questions and Answers: Over 400 Questions Most Often Asked by Parents. Compiled and Answered by the Children's Welfare Federation of New York City. General Chairman: John Fitch Landon, M.D. Cloth. Price, $2. Pp. 159. Doubleday & Company, Inc., Garden City, N. Y., 1948.

A panel of twenty-nine experts in child care under the direction of Dr. John F. Landon, attending pediatrician of the Roosevelt and Woman's Hospitals, New York, have given authoritative and simple answers to over four hundred questions that trouble and perplex parents. The questions were compiled and the book prepared under the auspices of the Child Health Committee of the Children's Welfare Federation of New York City. Questions and answers cover many of the simpler phases of growth, development, nutrition, emotional reactions and medical care of special senses, broken down into appropriate chapter headings for easy reference. Both questions and answers are couched in language easily understandable to the parent with average or less than average education and are designed to be as helpful to the parent as to the child.

The section on emotional guidance appears particularly good and tends toward the development of an easier philosophic relationship between parent and child. Sample, question 261: "How can a parent be patient at 5 o'clock?" Answer: "Realize that it is 5 o'clock and that is why you are not patient. This in itself will help."

In general, all chapters contain much information that will be helpful to parents, as the questions are compiled from those most frequently asked by parents and guardians about children in the 1 to 6 year age group. The questions are selected from a group submitted to the Children's Welfare Federation by over two hundred child health and welfare agencies in New York City for which the Federation acts as a coordinating organization.

A Textbook of Clinical Neurology with an Introduction to the History of Neurology. By Israel S. Wechsler, M.D., Clinical Professor of Neurology, Columbia University, New York. Sixth edition. Cloth. Price, $8.50. Pp. 829, with 162 illustrations. W. B. Saunders Co., West Washington Square, Philadelphia 5, 1947.

This well established and extensively used textbook of neurology has come through in a new edition, the sixth, and a review of its contents reveals that extensive revision has indeed taken place. The greatest changes are seen in the sections on therapy, where the remarkable achievements of the sulfonamide drugs and penicillin are documented in the various diseases such as purulent meningitis, brain abscess and syphilis of the nervous system. Apparently the book went to press before a record was established for the application of streptomycin in some diseases. Perhaps this is just as well, since a long period of test is necessary before one is justified in including a new drug as standard treatment, especially in a textbook which is used by medical students.

Much of the old has been retained in the book, although the author has made a strong attempt to eliminate the clinical pictures which are not too often encountered now. One would perhaps desire more emphasis on early symptoms or mild manifestations of some of these diseases. The chapter on electrical examination is essentially the same as that in the earlier editions, and this section perhaps could be improved by including some of the newer methods of electrical diagnosis which utilize tetanus ratios and electromyography.

In general, however, the "Textbook of Clinical Neurology" by Wechsler remains the friendly, interesting and easily read volume which every medical student and practitioner can utilize to advantage. It is actually almost encyclopedic in its contents, and one has only to know neurology to realize how much has been packed between the two covers.

Nouvelles techniques de traitement des fractures: Méthodes orthopédiques, réduction dans les cadres de traction, synthèses à minima; brochages, enclouages. Par H. Godard et R. Michel-Béchet. Préface du Professeur J. Leveuf. Paper. Price, 1500 francs. Pp. 406, with 206 illustrations. G. Doin & Cie, 8 Place de l'Odéon, Paris 6e, 1948.

This book covers many of the new technics employed in the treatment of fractures, including orthopedic methods such as reduction by traction, splints and intramedullary metallic pins, and nails. Some interesting experimental work on the physiology and biology of repair of fractures and osteogenesis after pinning and nailing is described; also a complicated apparatus and plaster for disjointed symphysis pubes instead of wiring through the obturator foramina.

The technic of Merle D'Aubigne, which we know as Dickson's, is illustrated. Fractures of the patella are given 2 pages. The French have little time for surgical repair and advise patellectomy.

The treatment of delayed consolidation and pseudarthrosis is discussed under the headings: medical; heterogenous bone graft; convalescent serum (Imbert); injections of colloidal suspensions, hormone therapy; intrafocal injections; testicular injections; splenic extracts; acidification; autohemotherapy; sympathectomy; Beck operation; morcellation of Kirschner, and the use of os purum.

Detoxication Mechanisms: The Metabolism of Drugs and Allied Organic Compounds. By R. Tecwyn Williams, Ph.D., D.Sc., Senior Lecturer in Biochemistry, University of Liverpool, Liverpool. Cloth. Price, $5.50. Pp. 288. John Wiley & Sons, Inc., 440 Fourth Ave., New York 16, 1947.

The principal title of this book is misleading, since the bulk of the discussions relate to the metabolism of various drugs and chemicals. Furthermore, many of the reactions which drugs undergo in the body and which are classed as detoxication mechanisms actually result in the formation of substances more toxic than the parent compound. Thus the sulfonamide compounds are converted to the acetyl derivatives, ethylene glycol is converted to oxalic acid, and methyl alcohol is converted to formaldehyde and formic acid.

This volume represents an excellent and exhaustive compilation of the available knowledge on drug metabolism. The arrangement of subject matter is by chemical classification and the chemical phases of the subject are emphasized. An excellent bibliography is included. This book should be on the shelf of all biochemists, physiologists and pharmacologists.

Public Health Law. By James A. Tobey, Dr.P.H., LL.D. Third edition. Cloth. Price, $4.50. Pp. 419. The Commonwealth Fund, 41 E. 57th St., New York 22; Oxford University Press, Amen House, Warwick Square, London, E. C. 4, 1947.

This is a third edition of a work initially published in 1926. It has been expanded to include recent alterations in governmental organization and administration, important legislative trends and approximately two hundred and fifty new court decisions relating to various aspects of public health law. It is designed to make readily available to health officers and others engaged in public health activities authentic information for their guidance. The author has had training in the fields of both public health and law. That fact is reflected in the contents and arrangement of the book, and its quality entitles it to a wide circulation. In the preface to this edition, the author expresses the hope that the book may continue to serve a useful purpose in the interpretation of law to the public health officer and of public health to the lawyer and the judge. There is justification for that hope.

Theory and Practice of Body Massage. By Frank Nichols. Cloth. Price, $4. Pp. 213, with 150 illustrations. Milady Publishing Corporation, 3721-23 White Plains Ave., New York 67, 1948.

This is primarily an instruction book for persons of limited education who aspire to become operators of massage parlors. It attempts to cover a wide range of medical subjects, such as anatomy and physiology, classification and physiologic effects of massage, art and practice of massage, hydrotherapy, therapeutic and "reducing" exercises, advice on constipation, use of depilatories and diets, and ends with a few pages on "professional ethics." Hardly worth a review in a medical journal.

Safety for the Household. U. S. Department of Commerce, National Bureau of Standards, Circular 463. Paper. Price, 75 cents. Pp. 190, with illustrations. Supt. of Doc., Government Printing Office, Washington 25, D. C., 1947.

This is a paper-bound volume prepared by the United States Bureau of Standards and designated as Circular 463, published by the United States Department of Commerce. As indicated in the title, it deals with safety in the home, starting out with statistics, suggestions for instruction to children, comments on organized safety and a list of publications for the householder. It then deals in turn with chemical hazards, which include acids and caustics; cosmetics, drugs and medicines; fumigants, disinfectants and insecticides; paints, varnishes, lacquers and enamels; polishing and cleansing materials, and refrigerants. Contamination of food and water also is discussed. Next come chapters on electrical hazards, fire hazards, gas hazards, lightning, mechanical devices, yards and gardens, miscellaneous hazards and suggestions for building a home. There is a chapter on first aid and some statistical tabular material relating to the accident hazard.

Law and the Practice of Nursing. By Nettie D. Fidler, R.N., B.A., Assistant Professor of Nursing, School of Nursing, University of Toronto, Toronto. In collaboration with Kenneth G. Gray, K.C., M.D., B.Sc. Cloth. Price, $2. Pp. 106. The Ryerson Press, 299 Queen St., W., Toronto 2, 1947.

Much of the contents of this readable little book relates to Canadian law and practices and for that reason will not be of particular value to the nursing profession in the United States except perhaps to permit a comparison of the conditions in the two countries. The authors have included chapters on the patient, physician and nurse relationship, on the relationship of the nurse to the hospital, on the laws of Canada, both federal and provincial, relating to drugs, on the duties of nurses relating to the mentally ill and to public health activities and concludes with an account of the development of the organized nursing profession in Canada.

Woman's Inside Story. By Mario A. Castallo, A.B., M.D., F.A.C.S., Associate Professor of Obstetrics and Gynecology, Jefferson Medical College, Philadelphia, and Cecilia L. Schulz, R.N. Cloth. Price, $3. Pp. 203, with 16 illustrations. The Macmillan Company, 60 Fifth Ave., New York 11, 1948.

This book of some 200 pages, written for the laity, is the first book of its sort that the reviewer is willing to advise his own patients to buy. The senior author has obviously had an extended experience in obstetrics and gynecology and has tried to answer the many questions asked by patients. Medical terms are omitted, and it is written in a language that the patient can understand. In eleven chapters, ovulation, fertilization, childhood, puberty, sex life, marriage, tumors, menopause, sterility, venereal disease, etc., are adequately covered. It is a book that should be read first by the girl in her early teens and then every decade.

Medizinische Terminologie: Wörterbuch der gesamten Medizin und der verwandten Wissenschaften. Von Dr. Med. Rudolf Abderhalden. Cloth. Price, 32 Swiss francs. Pp. 1213. Grune & Stratton, Inc., 381 Fourth Ave., New York 16; Benno Schwabe & Co., Klosterberg 27, Basel 10, 1948.

"Medical Terminology," compiled by R. Aberhalden, is a medical dictionary comparable to our standard texts. It is not as all inclusive as, for example, Dorland's, and with a single exception contains no illustrations. It appears to fill an important place in the German medical literature, for, as the author points out, there have been no German medical dictionaries published for a number of years. A novel feature from the point of view of a German author is the inclusion in the dictionary of terms belonging to the related sciences such as physiology, physics, botany and physiologic chemistry in particular. Although limited in scope, the dictionary impresses one as a valuable contribution to German medical literature.

Dictionnaire de spécialités pharmaceutiques 1948. [Including] Nomenclature de spécialités pharmaceutiques classés par laboratoires. (Parties 1 et 2). Par Louis Vidal. Twenty-fourth edition. Boards. Pp. 2114; 68. Office de Vulgarisation Pharmaceutique, 11, rue Quentin-Bauchart, Paris, 8e, 1948.

The last edition of this book on pharmaceutic specialties appeared in 1946. Obviously it is of most interest to those who desire information on the composition, source of supply and other pertinent information on drugs sold abroad. It cannot in any possible sense be called a therapeutic guide but would be useful for those who try to maintain complete libraries, for those who from time to time have inquiry concerning the identity of foreign preparations and for those whose clientele includes persons recently from European areas.

Union internationale thérapeutique. Journées thérapeutiques de Paris 1946. Sous la présidence du Professeur M. Loeper et du Dr L. Bory. Fer, voie pulmonaire en thérapeutique (les aérosols). Paper. Price, 980 francs. Pp. 475, with illustrations. G. Doin & Cie, 8 Place de l'Odéon, Paris 6e, 1948.

This is a series of articles and discussions divided into two parts, the first being devoted to the use of iron, the second to aerosol administrations. The articles are in French, but embrace a fairly extensive list of topics. While the book will be of limited value to most members of the medical profession, it may have some usefulness for those who attempt to maintain complete libraries.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

"DICUMAROL"

To the Editor:—If the determination of prothrombin time is the only measure for dosage of "dicumarol" in coronary thrombosis, no patient who is treated at home can be given this drug. A determination which could easily be made is the coagulation time. Is there any correlation between prothrombin time and coagulation time? At what coagulation time should "dicumarol" therapy be discontinued? My object is to be able to give "dicumarol" during the first eight or ten days when there is danger of mural thrombi, instead of not at all.

Max Kunreuther, M.D., Bronx, N.Y.

ANSWER.—Although recent reports indicate that the administration of "dicumarol" following a myocardial infarction may reduce the incidence of complications due to intravascular thrombosis, final proof awaits further statistical evidence. Daily determination of the blood prothrombin clotting time is necessary if "dicumarol" is to be used, as the dose of the drug depends on the extent of increase of the prothrombin clotting time. The whole blood coagulation time, even when accurately measured in a water bath at 37 C. by the Lee and White technic, does not reflect alterations in prothrombin time within the recommended therapeutic range. In fact, prolongation of the whole blood coagulation time does not occur unless the prothrombin activity is below about 10 per cent of normal. For this reason, measurement of the coagulation time is valueless in assessing the action of "dicumarol." Blood for the determination of prothrombin time may be drawn in the home—(4.5 cc. of blood mixed with 0.5 cc. of 0.25 per cent sodium citrate solution)—if no longer than one hour is allowed for transportation to the laboratory.

Q FEVER

To the Editor:—An employee of a local packing plant has cryptogenic fever. To eliminate Q fever from the differential diagnosis, we would like to have a complement fixation test for Rickettsia burneti. Where can we do this, and what are the special procedures? How long can blood agar be kept and still retain its efficency for bacterial cultures?

John P. Darling, M.D., Mason City, Iowa.

ANSWER.—The complement fixation test is the only practical procedure for the diagnosis of Q fever. Requests for such tests may be made of the National Institute of Health, Bethesda, Md. Simultaneous tests made on two serums, one taken during the acute stage of the disease and one after recovery, are desirable. A definite rise in antibody titer is diagnostic. Where paired serums are not available, a significant titer in a convalescent serum sample is usually diagnostic.

No definite time limit can be set, beyond which blood agar loses its efficiency. Freshly prepared blood agar supports maximum growth. Thereafter, there is a gradual decrease with time in the number of organisms which grow in colonies. Poorly viable strains may be lost on twenty-four hour old mediums, whereas easily grown organisms may multiply on mediums several weeks old. Drying of the mediums is a factor; plates kept sealed last longer. For special work blood agar plates should not be over twenty-four hours old; for routine work they are frequently kept up to a week.

ROUTINE OOPHORECTOMY

To the Editor:—Is Crossen's advice to do routine oophorectomy when laparotomy is done on women past 43 or 44 years of age generally accepted?

A. C. Eitzen, M.D., Hillsboro, Kan.

ANSWER.—Gynecologists differ in their attitude concerning the removal of normal ovaries at the time a hysterectomy is done. Most of them believe in routine removal of the ovaries after a specific age, and this age is usually 45 years. However, a few gynecologists remove ovaries routinely as early as 40 years of age. Some specialists do not remove normal ovaries in any woman who is still menstruating, regardless of her age. The reason for removal of normal ovaries at the time of hysterectomy, or laparotomy for other purpose, in women in their forties is elimination of the possibility of development of cancer because malignant neoplasms of the ovaries have a frightful mortality.

LIGHTNING PAINS

To the Editor:—I have a patient who is tabetic and is troubled with "lightning pains." What is the best treatment?

S. E. Reynolds, M.D., Morehead, Ky.

ANSWER.—It is necessary to know the status of the spinal fluid of the patient, because among persons whose spinal fluid is active the probabilities are that 60 per cent of them will derive some relief from the lightning pains after treatment, in the sense that the pains will be less severe and the attacks will recur less often. In a tabetic patient in whom examination of the spinal fluid reveals no abnormality, irrespective of whether the return of the fluid to normal is the result of treatment or occurred spontaneously, the treatment of lightning pains is unsatisfactory. Vitamin B, administered both by mouth and by injection, has been of value in certain cases; likewise, some patients note that after an excess of sugar in their diet they will experience exacerbation of the pains, whereas others believe that the eating of excess amounts of meat tends to increase the frequency of occurrence of the pains. The presence of secondary infection—such as severe focal infection in tonsils or prostate gland, the common cold or any similar intercurrent infectious process—invariably aggravates the pains. The same may be true in certain persons in changes of weather. Frequently they can forecast a change in the barometer twenty-four hours in advance of the event, because of the attacks of pain they may experience.

Penicillin is of some help to these patients, to the extent that possibly a fourth of them derive some benefit from this agent. Other forms of antisyphilitic treatment, such as fever therapy and intraspinal treatments, have not been of so much help to patients whose spinal fluid has become normal as to those whose spinal fluid is active. Attempts to overcome the pains by the injection of various substances along the neural pathways have not been attended with success.

ACUTE GLOSSITIS

To the Editor:—A patient of mine has acute glossitis. He is about 50 years of age, and until one year ago never had difficulty of any sort. His tongue becomes extremely sore along the borders, and the tip of the tongue becomes tender. Examination reveals that the tongue is a beefy, fiery red along its anterior two thirds. The edge is more intensely red than the center. Results of routine laboratory procedures reveal that the blood and urine are normal. A gastrointestinal roentgen examination reveals normal conditions. Gastric analysis showed a mild hypochlorhydria. Ingestion of large doses of vitamins orally, including large doses of nicotinic acid, gave no relief. However, injection of 1 cc. of liver extract (10 units per/cc.) gives him relief within two to three hours. The pain in his tongue disappears, as does the inflammation. The tongue remains well for about three weeks, at which time inflammation recurs. His diet seems adequate, and he certainly does not have pernicious anemia or sprue. Apparently there is a failure to absorb an essential factor from the diet. Incidentally, an attempt to maintain him on folic acid did not prevent recurrence of the glossitis. It appears that only liver is useful, as massive doses of vitamin B complex intravenously and intramuscularly failed completely. Please discuss this problem.

J. J. Stark, M.D., Belpre, Ohio.

ANSWER.—Simple uncomplicated glossitis, as described, could have many possible causes. In an apparently healthy person the cause would probably be either a deficiency or a local irritant. Infection, an allergy or a neurogenic basis would probably not produce such a pure and discrete condition. From the information given, the glossitis would seem to be due to a deficiency, probably the lack of an unknown specific factor present in liver extract. Liver extract is composed of numerous chemical substances, the identity and action of which are not all known at present. Patients with evidence of a deficiency may fail to respond to certain factors (folic acid) but many respond to liver extract itself. There may even be differences in response to various methods of administration (Watson, J., and Castle, W. B.: *Am. J. M. Sc.* **211**:513-530 [May] 1946).

Several types of deficiency may produce an apparently identical glossitis. Lack of any of several members of the vitamin B complex, of certain unidentified factors and even of iron may be responsible and have been demonstrated to clear the glossitis, as well as an associated anemia, when administered.

The chance that there is an absorption defect is remote, especially when the intestinal function, roentgenologic status and gastric acidity are not abnormal. The acidity could well be rechecked, however, to be sure that the glossitis is not a preanemic occurrence.

Local irritants should be excluded as potential causes of the glossitis. Smoking, dental abnormalities, mouth washes, irritant foods and alcoholic beverages may produce low grade inflammation of the tongue, and the last-named may result in a deficiency (through diet).

It would seem from the history that the various vitamin B preparations have had an adequate trial and that the response to liver extract is not coincidental. (Nicotinamide should be *given in 50 to 100 mg. doses by mouth each day for three weeks.)* It would be valuable to know whether liver extract and whole liver by oral administration is effective in clearing the glossitis. It might be well to keep cirrhosis of the liver in mind and to be sure that the man's diet is actually adequate.

If all the points which have been suggested prove to be without value, tell the patient that he has an unusual condition and that he will need to continue treatment, as well as observation, for an indefinite period.

SYPHILIS

To the Editor:—A white man about 25 years of age with a positive reaction to serologic tests for syphilis was given several injections of penicillin while in the service, was released and was advised to see a physician in his home town. He has had some treatment but not with any regularity—possibly twelve injections of an arsenic preparation intravenously and about twenty-five of a bismuth compound intramuscularly. When he consulted me he had impregnated a girl and I have given both of them active treatment. To date both have had ten injections of 300,000 units of penicillin in oil and wax daily, twelve of neoarsphenamine 0.6 Gm. and twelve of a bismuth compound. Recheck serologic tests after this course give a strongly positive reaction for the man and slightly positive for the girl. By law in Ohio they are denied a marriage license. Am I right in authorizing the judge of the probate court to issue this certificate? How much more treatment should be given this couple?

M.D., Ohio.

Answer.—The history of the syphilitic infection and data on the original diagnosis would be helpful. In the presence of a negative history and normal physical conditions an occasional positive response to serologic tests is encountered as the result of nonspecific infections. Does this man present any physical findings now suggestive of syphilis besides the positive serologic tests? A spinal puncture should be done and the fluid carefully examined, including a Wassermann test. If the spinal fluid is positive he should be treated with malaria or hyperpyrexia and simultaneous intravenous penicillin. This treatment should be followed by aqueous intramuscular penicillin injections (50,000 units every three hours, total 5,000,000 units) and titrated blood serologic tests.

The pregnant girl should be observed for physical findings of syphilis and titrated serology tests. If the man has a positive spinal fluid, the girl should receive aqueous intramuscular penicillin (total 5,000,000 units) during the second or last trimester of pregnancy. Twelve biweekly intravenous injections of oxophenarsine hydrochloride (0.04 Gm.) and six intramuscular injections of an insoluble bismuth compound should be added to the course of penicillin. If the man has a negative spinal fluid test and negative physical findings, a course of aqueous intramuscular penicillin injections for the girl would suffice during the last trimester of pregnancy. A postpartum spinal puncture on the mother should be done. A serologic test on the cord blood and a monthly blood test on the infant should be carried out. With the foregoing precautions you would be justified in authorizing the judge of the probate court to issue a marriage certificate.

ANTHRALIN CREAM

To the Editor:—I have used anthralin cream (Abbott) 0.1 per cent for psoriasis, off and on for several years. I never have more than one or two small lesions usually over the tibia. Usually about one week's applications twice daily clear up the psoriasis. Now a lesion about 0.5 cm. in diameter has not entirely disappeared after three or four weeks of application. This lesion is pale and looks as if it will shortly clear up. Is anthralin carcinogenic and have human beings contracted cancer of the skin from its use? How long can one safely use it against psoriasis?

M.D., California.

Answer.—As far as can be determined, there are no known instances of human carcinoma in which anthralin has been shown to be an exciting or associated etiologic agent. However, it would be exceedingly difficult to prove conclusively that anthralin or any other similar agent was responsible for inducing malignant changes in cutaneous lesions unless such changes occurred frequently in association with anthralin medication.

There is a theoretic possibility that anthralin could, after long-continued application, induce metaplasia. Anthralin is closely allied chemically to anthracene. It is an irritant and its therapeutic action is based on its ability to stimulate epithelial proliferation. Regardless of this theoretic possibility, anthralin has not been demonstrated to have carcinogenic properties by actual animal experiments or by clinical experience.

THROMBOPHLEBITIS

To the Editor:—A man aged 40 has recovered from extensive thrombophlebitis involving the superficial veins of one leg, including the great saphenous vein. The patient is a barber, and after four or five hours of work 3 plus pitting edema of the lower part of the extremity develops. What is the prognosis in regard to spontaneous reconalization of the thrombosed veins with subsequent improvement in the circulation? What therapeutic measures can be exhibited to improve the return circulation? What are the possible complications, and what measures can be undertaken to prevent their occurrence?

M.D., Illinois.

Answer.—The physician always needs to consider the cause of thrombophlebitis in superficial veins. Insufficient evidence is included in the query to determine what the cause might be in the specific case under consideration. Thrombophlebitis occurs spontaneously; it affects varicose veins and it occurs in thromboangiitis obliterans, polycythemia vera and as a result of carcinoma, chiefly of the stomach, bronchus and pancreas. It is probable in the case under consideration that the thrombophlebitis was due to varicosities. Inasmuch as there is a substantial degree of swelling of the extremity when the subject is on his feet for long, it is probable that the femoral or the femoral and iliac veins were occluded by a thrombus. It is rare to have any substantial degree of edema from occlusion of a long saphenous vein by a thrombus.

The steps which should be taken in consideration of the history of this patient are (1) an attempt to determine the cause of the thrombophlebitis and (2) adequate support to the extremity to control the edema, in order to prevent the consequences of chronic venous insufficiency (edema, varices, chronic indurative cellulitis and stasis ulcer). The type of support which should be worn is determined entirely by its adequacy. If the ordinary cloth-elastic bandages available on the market prevent swelling, they are adequate; if they do not, a pure gum rubber bandage may be needed.

PHARYNGEAL OBSTRUCTION

To the Editor:—Please suggest further methods of investigation for the following case: A single white man aged 64 was in good health until six months ago, when he experienced difficulty in swallowing solid food. This has become gradually worse, and now he has severe pain requiring sedation with opiates. Pain starts in the throat in the region of the hyoid bone and radiates upward to the lower jaw, antrums and temples. He is existing on milk drinks and soups but has lost over 35 pounds (15.9 Kg.). There is no cough or hemoptysis. Tests including a gastrointestinal series, fluoroscopy, bronchoscopy, roentgen examination of chest, neck and sinuses, Wassermann and brucellosis agglutination are so far negative. Several laryngoscopies have not proved of help. Electrocardiographic tracings and the basal metabolic rate are both within normal limits. He has a few carious teeth, which are being removed one at a time.

W. F. Crosby, M.D., Sterling, Mass.

Answer.—The history suggests the following possibilities: (1) malignant tumor (the combination of obstruction and pain are most readily explained on this basis); (2) bulbar palsy (the history of obstruction is fairly characteristic for a bulbar palsy, but the pain is not easily explained on this basis); (3) chronic inflammatory disease with ulceration, and (4) foreign body, diverticulum with foreign body or benign stricture (remote possibilities).

The following procedure is suggested:

1. Additional details should be obtained from the history regarding the rapidity of onset and the progress of the obstruction, as well as the time of appearance and progress of the pain.

2. Careful external examination of the neck and supraclavicular and infraclavicular regions should include inspection and palpation. Local examination of pharynx, hypopharynx and larynx should be accomplished by the indirect method.

3. Fluoroscopic examination of the pharynx and esophagus should be made both during swallowing and during the performance of the Valsalva maneuver in the anteroposterior and straight lateral positions. Note any abnormality of the action of the palatal, pharyngeal and upper esophageal musculature that might be associated with difficulty in swallowing.

4. Perform esophagoscopic examination with particular attention to the hypopharynx, pyriform fossae and upper part of the esophagus.

5. Routine laboratory work should include urinalysis, blood count, differential count, serology and sedimentation rate.

If there is an obstructive lesion in the pharynx or esophagus it should be demonstrable on fluoroscopic examination. In the case of a bulbar palsy, however, there are sometimes associated palsies, most often involving the larynx. The difficulty in swallowing may be demonstrable roentgenologically by use of the Valsalva maneuver. This test in the anteroposterior position may demonstrate a weakness and bulging of the pharynx on one side.

The history of severe pain located high in the throat suggests strongly an ulcerative lesion affecting the epiglottis or some other part of the hypopharynx.

REMOVAL OF EXCESSIVE HAIR

To the Editor:—In the removal of excessive hair by electrodesiccation, is there danger of bad after-effect? What is the best technic? I plan to use a "Birchter-hyfrecator" for source of current.

M.D., California.

Answer.—Electrolysis is the preferred method in removing superfluous hair. One applies a current of sufficient strength to destroy the hair follicle, and, if properly carried out, the treatment is followed by a smooth, almost invisible scar and total destruction of the hair. The majority of dermatologists prefer electrolysis to high frequency diathermy. High frequency current offers the advantage of a time saver as compared with electrolysis. However, one must have equipment manufactured for this specific purpose, as it requires apparatus with a special fine current control such as is not available in ordinary high frequency machines. The lack of such control not only involves a definite danger of destroying the hair follicle but may result in abscess and excessive scar formation. For description of the technic of electrolysis in detail refer to any standard textbook on electrotherapy. Briefly, the method consists of placing a delicate needle point within the hair follicle, with the needle parallel to the hair shaft, being careful to avoid puncturing the tissues. The needle then is activated with a current just sufficient to destroy the hair follicle. The hair is gently lifted out with hardly any pull. One should be careful not to remove at one sitting too many closely adjacent hairs or repeat the treatment in the same area before all reaction has subsided lest excessive scar formation may be produced.

The "Birchter-hyfrecator" is essentially a high frequency unit, creating by the use of a spark gap condenser circuit, a high frequence damped current. Unless it has a special fine current control there is danger of producing excessive scar formation, as the interval distinguishing destruction of hair follicle from destruction of the skin is measured in a fraction of a second.

ESTROGENS AND SALT RETENTION

To the Editor:—Occasionally cardiopathic patients who are taking estrogenic substances are thrown into cardiac failure, presumably because these substances cause retention of salt and water in the body. Are there any estrogenic substances which do not possess this property?

Samuel L. Immerman, M.D., Philadelphia.

Answer.—Most potent estrogens are capable of causing a retention of salt and water in the body when administered in the appropriate dosages. There is little evidence at present to indicate whether there is a quantitative difference in this property among the common estrogens. It does seem likely, however, that those estrogens which are absorbed rapidly into the bloodstream will be most effective in causing retention of sodium with the increase in extracellular fluid. For this reason it is suggested that oral estrogens be used most cautiously in patients with cardiac damage. There is little possibility, however, that the injection of a slowly absorbed estrogen such as estradiol dipropionate, diethylstilbestrol *di*palmitate or estrone in aqueous suspension will cause any significant retention of salt and water when administered in therapeutic doses.

CHOREA

To the Editor:—A young married woman aged 25 has had several attacks of chorea since the age of 6. The last attack occurred during pregnancy and was so severe that she had to be aborted. Heart lesions are absent. A difference of opinion exists between the neurologist and obstetrician as to whether this woman should become pregnant again. Please give an opinion.

Louis Pelner, M.D., Brooklyn.

Answer.—A patient who has had several attacks of chorea without damage to the heart warrants thorough investigation. Is it chorea? Some recent literature tends to separate chorea from heart disease. This may be a psychiatric problem. If the condition is chorea and there is definitely no cardiac damage, no reason prevails to make pregnancy unwarranted.

PROCAINE IN ASTHMA

To the Editor:—Has procaine been used intravenously in the treatment of bronchial asthma? What is the intravenous dose of procaine hydrochloride when it is used alone or with other drugs?

R. C. Hill, M.D., York, Ala.

Answer.—Procaine has been used intravenously in the treatment of asthma. D. State and O. H. Wangensteen (The Journal, April 13, 1946, p. 990) described its beneficial effects in 14 of 16 patients with serum sickness and 6 of 7 patients with urticaria. One patient with chronic asthma failed to obtain relief. In patients with chronic urticaria the individual injection produced only temporary benefit. The dose used was 1 Gm. procaine hydrochloride dissolved in 500 cc. normal isotonic sodium chloride solution, given intravenously over a period of two hours. In other reports on the use of this drug against urticarial reactions the same dose was generally used. Durieu, DeClercq and Duprez (*Acta clin. belg.* **1:**150 [March] 1946) treated 25 asthmatic patients with intravenous procaine, employing 5 to 20 cc. of a 1 per cent solution daily. They stated that preliminary oral administration of phenobarbital improves the tolerance for procaine. They obtained lasting improvement in one half of the acute cases; 30 per cent of patients having emphysema with chronic bronchitis showed temporary improvement.

George L. Waldbott (The Journal, April 26, 1947, p. 1301) called attention to possible dangers from intravenous use of procaine because of allergic or toxic reactions and cited a near fatality from an injection of 0.5 Gm. of the drug by another physician. The evidence at hand would indicate that there is some hazard from the use of procaine intravenously and that this hazard would be increased in patients receiving repeated injections. It is questionable whether the effects thus far obtained justify this hazard.

EPIDIDYMITIS

To the Editor:—A man aged 34 who had acute gonorrhea about seven years ago was treated with sulfadiazine (or sulfathiozole). Before being pronounced cured by a urologist he had sounds passed and prostatic smear made. He had no difficulty until about one and one-half years ago when he got acute left epididymitis. The epididymis swelled to the size of an almond. He was treated with sulfadiazine for ten days (or two weeks) and had three injections of penicillin in oil and wax —300,000 units on successive days. The swelling subsided, and on rectal examination the left seminal vesicle was slightly distended and the left lobe of the prostate slightly soft. A few clumps of white blood cells were present in the prostatic smear. The prostate was massaged weekly for about two months, and the patient felt fine. The left epididymis became slightly tender and "ached" at various times. Prostatic massages were started again, but the smears showed only a few pus cells; no benefit was noted as far as the epididymis was concerned. Hot sitz baths were used and diathermy to scrotal contents was also given without benefit. All treatment was then stopped for a few months. About eight months ago typhoid vaccine along with penicillin in oil and wax was given on three occasions in ten days time. Fevers of 102 to 104 F. were obtained with no relief to the tender epididymis. The tender part of the epididymis is a small pea-sized nodule at the head which is firm and rather rubbery in consistency. In the past four to five months the patient has had joint pains in the hands—mainly the metacarpal joints and phalanges. Pains become worse on use of the hands—as in a sport or carrying a heavy package. The patient has a mild chronic sinusitis (postnasal drip) with occasional flare-up. No other focus of infection can be found. Roentgenograms of the sinus are normal; the sedimentation rate is 9 mm. in one hour; the white blood cell count is 8,700, with polymorphonuclears 57, small lymphocytes 34, large lymphocytes 1, eosinophils 4 and mononuclears 4. 1. Is it likely that the joint pains come from the epididymis? If so, what can be done for it? Can anything short of epididymectomy be done and would this operation be advisable? 2. What can be done for the tenderness of the epididymis? Has procaine infiltration of the epididymis been tried, and is it wise to try it?

M.D., Connecticut.

Answer.—Persistent tenderness in the epididymis subsequent to infection is not uncommon. No evidence of infection may be present in the prostatic secretion or in the urinary tract. Sometimes the discontinuance of local therapy and the use of a support for a period of a few months is definitely helpful. If the condition is painful and annoying to the patient over a period of many years after the acute infection, surgical treatment would seem to be indicated. In some of these cases a vasectomy on the affected side may be beneficial, and it is worthy of trial. If it is not successful, an epididymectomy should be considered. Procaine injection of the epididymis would hardly give any permanent relief. It does not seem probable that the pains in the hands of which the patient now complains are related to the epididymitis. If the infection in the epididymis is treated as outlined, it would be of interest to see whether it will have any bearing on the joint pains.

DRASTIC FOOD RESTRICTION

Effect on Cardiovascular Dynamics in Normotensive and Hypertensive Conditions

JOSEF BROZEK, Ph.D.
CARLETON B. CHAPMAN, M.D.
AND
ANCEL KEYS, Ph.D.
Minneapolis

Since the first description of essential hypertension by von Basch[1] in 1874 there has been a constant stream of regimens for the cure or amelioration of the disease. None has proved specific, but one of the most frequently recurrent has been dietary limitation in one form or another. The most recent upsurge of interest in the dietary treatment of hypertension appears to have been stimulated by Kempner's reports[2] indicating that beneficial results may be obtained with a diet containing about 2,000 calories, 15 to 20 Gm. of protein and 0.25 to 0.4 Gm. of sodium.[2] The precise effective feature of the diet remains in some doubt, but Grollman and his co-workers[3] and Bryant and Blecha[4] expressed the belief that it is sodium chloride restriction, first suggested for the treatment of hypertension by Ambard and Beaujard[5] in 1905 and vigorously supported in this country by Allen and Sherrill[6] since 1920. The role of caloric restriction in the Kempner regimen is difficult to evaluate, although there is considerable evidence from other sources[7] that simple limitation of calories, without particular attention to the sodium intake, often results in lowering of the blood pressure both in persons with hypertensive disease and in normal persons.

It is perhaps not entirely fortuitous that renewed enthusiasm for dietary limitation as a means of treating hypertension should follow so closely on the heels of a global war. With conditions of famine prevailing in so many parts of the world, many opportunities for studying the effects of starvation on hypertensive disease have arisen. Wherever it has been possible to make sufficient observations on populations living under conditions of starvation and drastic food restriction, much highly pertinent information has accrued. Supplementing such contributions is a mass of data obtained from a study of experimental drastic food restriction carried out as a wartime research project in this country. The combined sources offer little new with regard to the familiar and often salutary effect of loss of body weight in hypertension, nor do they establish whether it is the diminished intake of calories or of sodium that effects the reduction in blood pressure. In general, however, they provide considerable support for the treatment in certain cases of hypertension by vigorous dietary limitation. In addition, important new light is thrown on cardiovascular dynamics during and after drastic food restriction.

It appears to us that in vivo investigations of the type to be described bear much more directly on the therapeutic rationale of dietary limitation than does the in vitro study offered by Kempner.[2b, c] Further, much of this information is at present either unavailable or inaccessible to American readers. For these reasons we have undertaken to draw the salient features together in the following review.

CARDIOVASCULAR DYNAMICS DURING STARVATION AND DRASTIC FOOD RESTRICTION

Experimental Data; Minnesota Experiment.—The exact effect of loss of body weight on the circulatory status of normotensive persons has recently been demonstrated under well controlled conditions.[8] Thirty-four young men, previously normal in all respects, were subjected to rigid control observations for three months, after which their food intake was drastically restricted for an additional six months. The daily caloric intake for the period was slightly less than 1,600 calories; the daily intake of protein was 49 Gm., and, although the exact intake of sodium is not known, no attempt at sodium limitation was made. Under these conditions, the average body weight for the group (69.4 Kg. in the control period) fell 23.9 per cent in the six month period. Paralleling the decline in body weight were striking decreases in blood pressure, pulse

rate and basal metabolic rate. The mean systolic blood pressure for the entire group fell from 106.5 mm. to 94.7 mm. of mercury, a decrease of 11.1 per cent; the corresponding values for the mean diastolic pressure were 69.9 and 64.5 mm. of mercury, respectively, representing a decline of 7.73 per cent during the six months of limited food intake. The mean pulse rate for the group at the end of the period reached the astonishingly low value of 37, and the basal metabolic rate reached a final average of — 39.9 per cent on the Mayo scale. An equally striking decrease in the size of the heart, progressing as semistarvation proceeded, was observed.

These and other observations point unmistakably to a general depression of circulatory function in previously normal young men with vigorous limitation of food intake. This depression is not to be confused with circulatory failure. Although edema appeared during the six month period in almost all the subjects, there was no evidence at this time of dyspnea, increased venous pressure or cardiac dilatation.

TABLE 1.—*Data Obtained in the Minnesota Experiment* *

Item	Period						
	C	S24	R6	R12	R14	R16	R20
Systolic blood pressure (mm./Hg.).............	105.3	92.7	97.2	101.5	106.8	104.9	104.0
Diastolic blood pressure (mm./Hg.).............	70.1	63.3	66.5	69.2	72.5	70.0	68.8
Venous pressure (cm./saline solution)....	(10)	4.8	5.5	6.7	—	11.4	11.0
Resting pulse rate (beats/min.)............	56.1	37.8	42.7	52.3	70.9	64.1	57.3
Daily food intake (calories)................	3,692	1,647	2,458	3,527	5,801	5,271	3,950
Body weight (Kg.)....................	67.7	51.7	53.0	58.2	64.5	68.5	70.8
Basal oxygen consumption (cc./min.).......	228	145	158	186	253	253	239

* Mean values of arterial and venous blood pressure, resting pulse rate, daily food intake, body weight and basal oxygen consumption for 12 men studied in the Minnesota semistarvation-rehabilitation experiment during the control period (C), after twenty-four weeks of drastic food restriction (S24) and six (R6), twelve, fourteen, sixteen and twenty weeks of nutritional rehabilitation.

Observations on European Populations During World War II.—Roughly corresponding to the three phases of the Minnesota Experiment (control, semistarvation and rehabilitation) are observations made in Leningrad before the outbreak of war, during the period of severe dietary limitation (September 1941 to March 1942) and during the recovery phase following the partial lifting of the siege in the spring and summer of 1942.[9] This study is of particular interest in that, unlike the Minnesota experiment, it encompassed both sexes and all adult age groups.

A decrease in the blood pressure was one of the characteristic symptoms of semistarvation in Leningrad, as were emaciation, muscular weakness, subnormal temperature, sensitivity to cold, general fatigue and apathy, polyuria and bradycardia.

It appears that during the period of reduced food intake not only was there a reduction in the number of patients hospitalized for hypertension but there were also significant changes in the clinical picture of hypertension and its manifestations. In a large number of patients who exhibited long-standing chronic hypertension, the blood pressure was reduced to a normal or near normal level. Furthermore, symptoms commonly associated with hypertension, such as headaches, dizziness and dyspnea on exertion, decreased in intensity or completely disappeared. In addition to the lowering of blood pressure and amelioration of the manifestations of hypertensive disease in general, there was a definite decrease in the severity and frequency of other cardiovascular disorders, such as angina pectoris and myocardial infarction.

From various other parts of Europe have come reports of somewhat similar observations. In Holland, striking decreases in blood pressure and pulse rate were observed by Langen and Schweitzer,[10] and by Lups and Francke[7b] in the general population during the winter of 1944-1945, when dietary restriction was at its height. Leyton[11] reported a definite tendency toward hypotension among prisoners of war in a camp in Germany where conditions of semistarvation prevailed. Similarly, Zimmer and his co-workers[12] observed hypotension to be common among undernourished persons held in concentration camps in the unoccupied zone of France. Burger and his co-workers[13] and Mollison[14] supplied further evidence of the same type from Holland and Germany, respectively. Specific mention of the effects of starvation on the blood pressure in hypertensive persons is made by Lups and Francke.[7b] They observed a more or less pronounced decline in systolic and diastolic blood pressures in about 74 per cent of normal persons and 93 per cent of persons with hypertensive conditions who lost weight during the period of drastic food restriction in Holland (September 1944 to April 1945).

CARDIOVASCULAR DYNAMICS DURING RECOVERY FROM SEMISTARVATION

Experimental Data; Minnesota Experiment.—In the Minnesota project, as in the Leningrad experience, changes in cardiovascular dynamics during recovery from semistarvation were recorded in some detail. For the entire group of 32 subjects, after twelve weeks of controlled rehabilitation the average weight increased from 52.8 Kg. to 58.8 Kg. The caloric and protein intake for this period were 2,449 calories and 72.85 Gm., respectively. Slight but definite rises in systolic and diastolic blood pressures occurred during the period, but the average readings were still well below the control values.

Of particular interest are the data for a smaller group of 12 men, who were observed for an additional eight weeks during which the dietary intake was large but was not rigidly controlled. The data are summarized in table 1. A large increase in caloric intake following the twelfth week of rehabilitation was associated with a rise of both the systolic and diastolic arterial blood pressure to values slightly above the control values. There was also a rise in the average venous blood pressure, which in 4 men reached the level of 15 cm. of saline solution or more. Moderate tachycardia and dyspnea on exertion became common during the period of rapid gain in weight. All these data indicate that the decidedly increased food intake, resulting in an increase of body weight and associated with a decided rise in the basal metabolism, placed a considerable strain on the cardiovascular system.

The experience with 1 particular man further suggests that the subjects were, in fact, on the verge of congestive cardiac failure. This man was released from the experiment after twelve weeks of rehabilitation and immediately began to eat at the general level of 7,000 to 10,000 calories of food a day. The daily intake of thiamine and other members of the vitamin B complex was above adult requirements as currently estimated during the entire period of rehabilitation. Two weeks after his release from controlled rehabilitation the subject noted a sudden return of edema and complained of dyspnea on exertion. At this time it was observed that he had gained 9 pounds (about 4.1 Kg.) in the preceding two days. Laboratory examinations showed a plasma protein level of 6.3 Gm. per hundred cubic centimeters and a ratio of albumin to globulin of 1.75. The venous pressure was 20 cm. of water. The size of the heart was seen to have increased sharply in the two weeks following cessation of controlled rehabilitation. The subject was placed in bed and given restricted fluids, ammonium chloride and a diet of 3,000 calories a day. A few days later diuresis began, and he quickly lost 10 pounds (about 4.5 Kg.) of body weight, after which recovery was rapid.

Interesting data were obtained on a group of 19 men examined after thirty-three weeks of dietary rehabilitation. At this time the average body weight increased to 75.8 Kg., or 109.2 per cent of the prestarvation value. At the same time, the average systolic and diastolic values were 107.7 and 70.4 mm. of mercury, as compared with 104.1 and 68.6 during the control period. These average values do not reflect the trend of changes as clearly as the frequency with which the blood pressure changed in the 19 persons comprising the follow-up sample. The systolic blood pressure increased in 14 subjects, decreased in 4 and remained the same in 1. The respective frequencies for the diastolic blood pressure were 13, 5 and 1. In no case did the rise represent a pathologic shift in the level of the blood pressure—the maximum rise was 12 mm. of mercury—but the relative frequency of the increases is suggestive.

In a group of 7 men, examined fifty-eight weeks after the end of the vigorous dietary limitation, the weight returned close to the prestarvation level (69.3 Kg., or 101.4 per cent of the control value). At the same time, the average blood pressure also returned to prestarvation levels. The actual means for the systolic blood pressure during the control period and at the fifty-eighth week of rehabilitation were 107.9 and 107.2; for the diastolic pressure the respective values were 70.7 and 69.1 mm. of mercury.

Observations on European Populations in World War II.—It is evident, from the Minnesota work, that the decline in blood pressure that occurs during semistarvation in normal young men is a reversible pocess and that when recovery is fully established the blood pressure returns to normal values. From areas directly affected by the war comes evidence that not only does the blood pressure return to normal values during recovery but it may also overshoot the mark to frankly hypertensive levels. Episodes of hypertension were observed in malnourished British prisoners of war during the period of recovery from semistarvation.[15] Schwartz,[16] working with Spanish internees in France, reported the sudden development of moderate hypertension concomitant with the institution of treatment for semistarvation.

By far the most extensive study of cardiovascular dynamics in a population recovering from semistarvation was that done in Leningrad.[9] A brief summary of the observations during the second, or starvation, phase of this work has already been given.[17] The observations during the third, or recovery, phase were detailed, and the results appear to us to be important enough to warrant reporting at some length.

In the two years following the famine in Leningrad, hypertension suddenly became a major medical problem.

In April 1943, measurements of blood pressure were carried out on a large sample of the city population and on small samples from particular occupational groups. Specifically, some 10,000 "normal" persons were examined, and the results were compared with those of Hellman, who conducted a similar survey in the prewar year 1940. Taking 140 mm. of mercury as the upper limit of normal for the systolic and 90 mm. of mercury as that for diastolic blood pressure, a pronounced increase in the incidence of hypertension in all age groups was observed (table 2). Thus, it appears that the pool of persons in whom symptoms and clinical signs of hypertension are likely to develop was enormously increased during recovery from semistarvation. In the group aged 20 to 29 and in that aged 30 to 39 there was approximately a fourfold increase in the period 1942-1943 as compared with the prewar incidence. In the group aged 40 to 49 the increase was about twofold, and in the group aged 50 or more it was threefold.

Table 2.—*Incidence of Elevated Blood Pressure* in "Healthy" Persons in Leningrad, 1940 and 1942-1943*

Age Group (Yr.)	Prewar (Percentage)	1942-1943 (Percentage)
20-29	3	12
30-39	7	30
40-49	25	50
50-59	22	66
60 plus	23	70

* Above 140 mm. of mercury systolic and 90 mm. of mercury diastolic.

That a portion of the increase in the incidence of hypertension might have been due to changes in the population of the city as a result of the war was taken into consideration by the Russian workers. The wartime population was an older one and contained more

women than the prewar population, both of which changes are factors tending to increase the incidence of hypertension. It was the opinion of the Russian authors, however, that the entire increase in incidence of the disease would by no means be accounted for by changes in the age and sex distribution of the wartime population of the city. Detailed breakdowns by age and sex of the wartime sample are not given, but a rough grouping by age is provided, as shown in table 2. Unless the number of persons in the younger age group were extremely small it seems that the age factor could not, *per se*, account for the differences between the prewar sample and that examined in 1942-1943. As for the sex factor, we are told that 80 per cent of the 1942-1943 sample were women. That women are more subject to hypertension than are men is freely admitted, but differences in the incidence of the disease due to the sex factor alone, as judged by surveys in the United States,[18] are considerably smaller than those observed in the Leningrad surveys.

The studies on specific occupational groups involved rather small samples, but suggested that workers in the food industry, whose jobs during the siege gave them access to adequate or nearly adequate diets, subsequently suffered much less from hypertension than did those whose occupations were not concerned with food.

The general increase in incidence of hypertension resulted, as might have been expected, in a striking increase in the number of patients admitted to hospitals for hypertensive disease. The number of patients with hypertensive disease admitted in peacetime to the Therapeutic Clinic of the Pavlov First Medical Institute in Leningrad represented about 10 per cent of all admissions. This proportion increased slightly during the first months after the outbreak of hostilities (July to September 1941), dropped significantly during the period of severe dietary limitation (October 1941 to March 1942) and increased progressively from that time throughout 1943. In January of the latter year, patients suffering from some form of hypertension constituted 20 per cent of the total admitted; by June 1943, the figure had risen to 60 per cent (table 3).

TABLE 3.—*Relative Number of Patients Admitted for Hypertensive Disease to the Clinic of the First Medical Institute in Leningrad*

Period	Total Admissions (Percentage)
1940	10.0
July to September 1941	15.0
October 1941 to March 1942	2.0
April to December 1942	24.5
1943	50.0
January to April 1944	35.0

The general level of admissions for hypertension in 1943 was five times as high as that during the prewar year of 1940. It is probable that the criteria for admission to the hospitals changed radically during the siege, so that patients suffering from chronic, or even acute, nontraumatic ailments were cared for at home instead of being admitted to hospitals. It is not surprising, therefore, to see a pronounced decrease in the number of patients admitted for hypertension during the period of drastic food restriction. Furthermore, with the lifting of the siege, one might expect an influx of chronically ill patients who had previously been denied hospitalization. Such an influx could account for the increase in the number of patients with hypertensive disease admitted shortly after March 1942, at which time 20 per cent of the total admissions were for hypertension as compared with 10 per cent in 1940. The influx of such a backlog of patients with hypertensive disease might logically be expected to have spent itself within a few months and, in any case, could hardly explain the phenomenal influx reported for June 1943 (60 per cent of all admissions).

TABLE 4.—*Age Distribution of Patients Admitted to a Hospital in Leningrad for Hypertensive Disease*

	1938-1939		1942-1943		
Age Group	Number	Percentage	Number	Percentage	Percentage Difference
30-39	18	9	51	18	+9
40-49	54	27	96	32	+5
50-59	80	40	111	37	−3
60 and over	48	24	39	13	−9

The Leningrad population changed little in 1942 and 1943, yet it was during the latter year that the large increase in admissions for hypertension took place. If the shift toward an older population were alone responsible for the increased incidence of hypertension, one would expect the shift to be reflected in the ages of hypertensive patients admitted to the hospital. Actually the proportion of patients in the older age groups who were admitted for hypertension declined somewhat during this period (table 4). In another sample of 212 patients with hypertensive disease (25 men and 187 women) there was a similar shift, with a larger incidence among the younger age groups. The frequencies for samples of patients in 1939 and 1942-1943 are given in table 5.

In short, it appears probable from the data presented that the increase in admissions to a hospital for hypertension or for some manifestation thereof was an independent phenomenon and was not due exclusively to changes in criteria for admission or to changes in the wartime population of the city.

The increase in admissions to a hospital for hypertension was paralleled by the incidence of hypertensive disease observed at autopsy. At the Erisman Hospital in Leningrad, in the period from 1941 to early 1942, only 1.2 to 5.2 per cent of all autopsies were carried out in cases in which there had been hypertensive disease. In September 1942, about six months after it became possible to increase food supplies, the percentage began to increase rapidly, and by early 1944 it had reached 54.5 per cent.

Not only was there evidence for an increased incidence of hypertension during recovery from semistarvation, but there were also indications, particularly among hospitalized patients, that the disease was seen in a severer form than previously. Thus there was a pronounced rise in the relative frequency and severity of such symptoms as headaches, vertigo and syncope. The blood pressure itself, particularly the diastolic component, was said to be generally higher in hospitalized patients with hypertensive disease than it was in the same group before the war. For the epidemic period of hypertension (1942-1943), the diastolic blood pressure was 90 to 100 mm. of mercury in 20 per cent, 100 to 120 mm. of mercury in 60 per cent, 120 to 140 mm. of mercury in 10 per cent and above 140 mm. of mercury in 10 per cent. Unfortunately, the corresponding prewar blood pressure levels were not given. Ophthalmoscopic examinations disclosed that, while changes in the retinal vessels were only slightly commoner than before the war, changes in the retina itself, such as exudate and hemorrhage, were much commoner. Before the war the latter changes were seen in 23 to 25 per cent of patients hospitalized for hypertensive disease, while during the epidemic 70 per cent showed such changes. Frank neuroretinitis, including papilledema, was seen in 20 to 30 per cent of hospitalized patients with hypertensive disease, but could not be directly related to the height of the blood pressure. According to the Wagener and Keith classification,[19] these observations indicate that over one half of the patients admitted to the Russian clinic during the epidemic fell into group 3 and about one fourth into group 4 (malignant hypertension).

---

[18] Wetherby, M.: Blood Pressure in 5,540 Individuals, Ann. Int. Med. 6: 754-770, 1932.

The incidence of cardiac insufficiency in persons with hypertension appears to have increased decidedly. The data for one hospital are given in table 6. In many patients, particularly those suffering from hypertension of relatively recent origin, the onset of cardiac insufficiency was acute. Many persons so affected had been apparently healthy up to the time the acute symptoms appeared, usually in the form of true cardiac asthma. The occurrence of angina pectoris either before or during the bouts of decompensation was rare. In many cases, the onset of cardiac insufficiency appeared to be related to severe physical exertion, particularly in persons ordinarily pursuing a sedentary calling. Further, there appeared to be no relation between the duration of hypertension and the development of cardiac insufficiency in a given case, the syndrome having developed in many shortly after the appearance of hypertension. In a sample of about 400 patients aged 20 to 80 years, there appeared to be a significant positive relationship between age and the incidence of cardiac insufficiency.

Table 5.—*Percentage Incidence of Clinical Hypertension According to Age in Two Samples of Hospitalized Patients in Leningrad*

Year	Below 20	21 to 30	31 to 40	41 to 50	51 to 60	61 to 70	71 to 80	Total Number
1939..........	0	2.7	10.4	29.6	40.9	13.7	2.7	154
1942-1943......	0.9	4.7	16.5	36.3	25.0	15.2	1.4	212
Percentage difference..	+0.9	+2.0	+ 6.1	+ 6.7	−24.1	+ 1.5	−1.3	

At the same time, it should be noted that the average age in the group with hypertension of recent origin was 45 years, while in the group with long-standing hypertension it was 57 years.

Roentgenographic studies were carried out in 1943 on 250 patients with hypertension of recent origin. The size and configuration of the heart were normal in 25.4 per cent, left ventricular enlargement was seen in 57.6 per cent and generalized enlargement of the heart in 14 per cent. Electrocardiographic studies of the same 250 patients disclosed no abnormality in 12.2 per cent and changes ordinarily attributable to hypertension in 33.3 per cent. Left axis deviation was present in 14.6 per cent and right axis deviation in 9.8 per cent.

The venous pressure was measured in 121 patients with hypertensive disease in 1943 during recovery from semistarvation. Thirty-seven per cent showed distinctly elevated values. Unfortunately, correlations between venous pressure, on the one hand, and symptoms, physical observations and heart size, as determined by roentgenogram, on the other, were not given.

Table 6.—*Admissions for Hypertensive Disease, With and Without Cardiac Insufficiency, to the Therapeutic Clinic of the First Medical Institute in Leningrad*

	July-Dec. 1941	Jan.-June 1942	July-Dec. 1942	Jan.-June 1943	July-Dec. 1943
Total number of admissions........	20	4	37	155	168
With cardiac insufficiency...........	10	3	27	114	124
Without cardiac insufficiency.......	10	1	10	41	44

At autopsy cardiac hypertrophy was seen to be slight to moderate in the majority of cases in which death was due to hypertensive cardiac disease, and extreme hypertrophy was decidedly uncommon. In patients who died of semistarvation uncomplicated by hypertension the average weight of the heart at autopsy was 168 Gm., as compared with the normal average of about 300 Gm. When hypertension was superimposed on semistarvation at Leningrad, the expected cardiac atrophy appears to have been modified by a tendency to relative cardiac hypertrophy. In patients with hypertensive disease who still showed pronounced effects of semistarvation, the average weight of the heart at autopsy was 370 Gm., with a minimum weight of 200 Gm. In a group of patients with hypertensive disease in whom the residue of semistarvation was less severe, the average weight of the heart at autopsy was 420 Gm., while in patients who died of hypertension uncomplicated by semistarvation it was 477 Gm. In late 1942 and early 1943, autopsies disclosed that of persons who died as a result of hypertensive disease, 78 per cent showed cardiac insufficiency and 14 per cent showed cerebral hemorrhage. Significant renal changes were seen in less than 35 per cent of the cases, while before the war nephrosclerosis of significant degree was observed in about 50 per cent of cases. Frank malignant nephrosclerosis (arteriolar necrosis) disappeared completely and did not begin to reappear until the second quarter of 1943. Roughly comparable American figures[20] show that about 50 per cent of patients suffering from hypertension ultimately die of congestive cardiac failure, 15 per cent die of coronary sclerosis, 15 per cent of cerebrovascular accidents and 8 per cent of uremia. Evaluation of the Russian data is hampered by the inadequacy of prewar figures for comparison and by the failure of the authors to present a complete description of the autopsy material. The autopsy data are nevertheless interesting when considered along with the clinical material. The suggestion that in the epidemic of hypertension following semistarvation in Leningrad, cardiac insufficiency increased decidedly while renal damage decreased is of the greatest interest, as is the reported virtual disappearance of malignant nephrosclerosis. It is regrettable that more information is not presented on these topics.

COMMENT

That drastic dietary restriction causes a fall in blood pressure in most normal persons and persons with hypertensive disease seems to us to be proved. In this connection the Minnesota experiment supplies unequivocal data as regards normal young men. The European observations, and particularly those made in Leningrad, supply almost equally impressive evidence as regards normal persons and persons with hypertensive disease of all ages and both sexes. Neither group of observations can be regarded as settling the controversy over the relative importance of caloric and sodium restriction in the lowering of the blood pressure. If anything, they suggest that caloric restriction may be fully as effective as sodium restriction in producing this result, since in neither the Minnesota experiment nor the Leningrad experience was the sodium intake specifically limited. In fact, the men subjected to experimental limitation of food intake increased their consumption of salt.[21] Those Europeans who were forced to endure drastic food restriction during the war probably received less sodium in the form of common salt than they did under prewar conditions; it is unlikely, however, that their sodium intake even approached the low level required by the Kempner regimen.

The increase in incidence and severity of hypertension during recovery from semistarvation that figures so prominently in the report from Leningrad seems too impressive to be ignored. The absence of frank hypertension during the recovery phase of the Minnesota experience may well have been due to the fact that the subjects employed were normal young men; in Leningrad, on the other hand, the observations embraced a population containing both sexes and many elderly persons. It appears not unreasonable that the hypertensive effects of refeeding may be more pronounced in a population containing both sexes and all age groups than in one composed entirely of normal young men. However this may be, both sources supply information indicating that the cardiovascular dynamic state during recovery from semistarvation may be extremely precarious, even in the absence of hypertension. As the Leningrad physicians pointed out, if hypertension be superimposed on this treacherous state, severe cardiac failure may result.

From a practical point of view there is much to be learned from the results of the Minnesota and Leningrad investigations. Both appear to lend support to the treatment of hypertension by vigorous dietary restriction. On the other hand, both suggest that the uncritical application of regimens like that introduced by Kempner may not be without some danger to the patient. It may be argued that the Kempner diet is not comparable to those prevailing during the phase of vigorous dietary limitation of the aforementioned investigations, since patients receiving the Kempner regimen are allegedly in caloric and nitrogen balance. The matter cannot be regarded as settled, however, and Fishberg's assumption[22] that the inevitable unpalatability of salt-poor diets results in caloric restriction probably has some basis in fact. It is possible that both sodium and caloric restriction, working together or individually, may cause lowering of the blood pressure and that both factors were at work during the phase of drastic food restriction of the Minnesota and Leningrad investigations. In any case, few workers familiar with the Kempner and similar diets will deny that patients frequently cannot or will not adhere to such restrictions. Out of the Minnesota and Leningrad experiences grows the possibility that such a patient may be worse off, when he modifies or abandons his dietary restrictions, than he was before the treatment was instituted. This possibility appears to us to make careful selection of patients to be treated by the Kempner regimen mandatory. Patients so selected should be warned beforehand that once instituted, the regimen must be followed carefully and that modifications, particularly if sudden, may be dangerous. There can be no objection to the regimen in severe and especially in malignant hypertension. For less severe disease, particularly in obese persons, it seems unwise to employ such severe dietary restrictions. The salutary effect of weight loss alone in such cases has been repeatedly demonstrated, and a reduction diet rather than a diet of the Kempner type is to be preferred.

SUMMARY

Recent experimental and epidemiologic observations indicating that drastic food restriction usually causes lowering of the blood pressure in normal persons and in persons with hypertensive disease are reviewed. The same reports also indicate that during recovery from semistarvation the cardiovascular dynamic balance is so disturbed that cardiac failure may occur. The blood pressure in previously normal persons returns to normal levels during recovery from semistarvation and in some instances, according to European reports, may go well above the upper limits of normal. Particularly striking are descriptions of an epidemic of hypertension and hypertensive cardiovascular disease which occurred after the lifting of the siege of Leningrad in 1943.

The bearing that these observations may have on the currently popular method of treatment for hypertension by severe dietary limitation is discussed.

Jenner and Hunter.—During this part of his career when he was actively engaged in his practice, he found time to conduct many biological experiments, some of which were suggested by Hunter. In fact, Hunter rarely wrote without some reference to this work. Jenner had occasion to send Hunter patients from time to time for his opinion and the report on these is accompanied by requests for biological material or suggestions of experiments which might help to solve some biological problem. He studied the subjects of the torpidity of hibernating animals and migration of birds; he introduced an improved method of purifying tartar emetic and conducted experiments on the effect of animal manure on vegetation. He showed "it was first the robin, not the lark, as has been generally imagined, as soon as twilight has drawn the imperceptible line between night and day, who begins his lonely song."—Milling, T., M.D., *The Bristol Medico-Chirurgical Journal,* Vol. 65, No. 233 (1948).

ACUTE CIRCULATORY ARREST

From Ventricular Fibrillation for Twenty-Seven Minutes, With Complete Recovery

R. STARR LAMPSON, M.D.
WILLIAM C. SCHAEFFER, M.D.
and
JOHN R. LINCOLN, M.D.
Hartford, Conn.

The catastrophe of sudden circulatory arrest in the operating room is an emergency which will confront almost every surgeon at least once during his career. It has been stated[1] that a busy surgical clinic may expect approximately 2 cases a year. Experience,[2] experimentally with animals and clinically with patients, has shown that sudden circulatory arrest may be due either to cardiac standstill[3] or to ventricular fibrillation.[4] The series of events which precipitate abrupt circulatory arrest are complex and open to speculation. It should be emphasized that in the reported cases this calamity occurred most often during light anesthesia in either the phase of induction or recovery, when the myocardium is known to be more irritable than normally.[5] Effective methods of treatment are now at hand, and prompt treatment may prevent an otherwise certain fatality. It is the purpose of this communication to take up briefly these measures and to report a case of proved ventricular fibrillation with complete recovery following direct cardiac massage and the intravenous administration of procaine hydrochloride.

The most essential single therapeutic measure in sudden circulatory arrest is the immediate restoration of the circulation. The administration of oxygen in high concentration by pulmonary resuscitative procedures is of paramount importance in order to maintain adequate oxygenation of the lungs and also to aid in the circulation of the blood.[6] It is apparent that in some cases of sudden cardiac arrest effective cardiac action has been promptly restored by the stimulation of cardiac palpation.[7] In ventricular fibrillation this is less likely to occur,[4] and the circulation must be maintained by prompt manual propulsion of the blood. Effective cardiac massage is necessary until defibrillation has been accomplished and forceful coordinated ventricular contractions are present. Ventricular defibrillation of the human heart in the presence of coronary disease has occurred spontaneously and has been recorded and reported.[8] At present there are two practical methods of interrupting ventricular fibrillation, namely, the use of electric shock, as recently reported by Beck,[9] and the administration of procaine hydrochloride into the blood stream. These two methods may be used separately or as adjuncts to each other.[10] For some time it has been recognized[10b] that procaine hydrochloride reduces the excitability of the hyperirritable myocardium. It has been administered to control cardiac irregularities during thoracic operations,[11] and it is also used prophylactically to prevent their occurrence.[12] The injection of epinephrine in sudden cardiac arrest should be reserved for the treatment of cardiac standstill and should not be used as an agent for defibrillation, because it makes a hyperirritable myocardium even more irritable. It is for this reason that electrocardiographic diagnosis is important, as it may determine which of two diametrically opposed drugs to use.

REPORT OF A CASE

J. R., a 7 year old boy, entered the Hartford Hospital through the accident room at 3:45 p. m., July 17, 1947, because of a deep laceration of the bottom of the right foot, which was sustained by stepping on a jagged piece of glass. The laceration extended through the sole of the foot and cut most of the nerves, muscles and tendons beneath the central portion of the arch. The loss of blood must have been only moderate, because the child showed *no* evidence of increased pulse rate, pallor, sweating or any other sign of shock. After receiving preoperative medication of 1/12 grain (54 mg.) morphine sulfate, 1/200 grain (0.325 mg.) atropine sulfate and 3/4 grain (48.8 mg.) "seconal sodium" (sodium 5-allyl-5-[1-methylbutyl] barbiturate), he was taken to the operating room for suture of the laceration. The pertinent portions of the operative note, which follow, describe the dramatic events which took place when the heart suddenly went into ventricular fibrillation.

During anesthesia produced by open drop ether induced with cyclopropane (fig. 1), the severe laceration of the plantar surface of the right foot was carefully cleaned with soap and water and then irrigated with 1 liter of isotonic sodium chloride solution. The wound extended across the foot, directly beneath the instep and down to the bone and completely divided the tendinous and muscular structures. Repair of the various structures, including tendons, muscles and nerves, was undertaken. During the procedure, which lasted about one hour and fifteen minutes, a blood pressure cuff was used as a tourniquet and was released every twenty minutes for two minutes.

At the close of the operation, when administration of the anesthesia had been stopped and while preparations were being made to apply a plaster boot, the patient's pulse abruptly stopped. Auscultation over the heart revealed absolutely no heart sounds. The patient became pale and ashen. Spontaneous respirations ceased. It became startlingly evident that this child had suffered sudden circulatory arrest. As soon as this fact was comprehended with certainty, which was approximately two and a half minutes, three minutes at the outside, from

the time the pulse had stopped, an incision was made in the left side of the chest in the fifth interspace, opening directly into the left pleural cavity (fig. 2). This was done with the ungloved hand, because the gloves had been removed preparatory to applying plaster. It took approximately ten seconds to open the chest. It was possible to insert the middle and index fingers of the left hand and palpate the heart, which felt soft and lifeless. Visual examination of the heart disclosed the fine ripples of ventricular fibrillation passing aimlessly across the left ventricle beneath the pericardium. Cardiac massage was immediately started by intermittently compressing the heart against the sternum with the middle and index fingers of the left hand. This was done at a rate of approximately sixty times per minute. An observer at the wrist of the child could feel an effective pulse each time the heart was compressed. The anesthetist maintained artificial respiration with the anesthesia machine and supplied pure oxygen to the lungs. The patient's color and general appearance improved promptly after cardiac massage was begun. Epinephrine was ordered, but, before it was given, the advisability of its use was discussed by those of us in the operating room, and it was decided that an irritable heart would be made more irritable with epinephrine. It was not given. About fifteen minutes elapsed, during which time the heart failed to assume a normal rhythm. It was decided to give intravenously 3 cc. of a solution of procaine hydrochloride in 1 per cent concentration. Administration of isotonic sodium chloride solution had been started in the left saphenous vein at the ankle. A transfusion of blood was started, to provide more red cells to carry oxygen and to replace any deficit which might have occurred following the laceration of the foot, although no evidence of shock or excessive loss of blood had at any time been noted.

Fig. 1.—Anesthesia record.

An electrocardiographic machine was procured, and a tracing was made (fig. 3). The fluctuations of the galvanometer string were observed and gave the gross impression of ventricular fibrillation. Approximately twenty-six and a half minutes after the circulatory arrest had been noted, a second dose of 2 cc. of procaine hydrochloride was given. In approximately thirty seconds after this, the tone of the heart changed. It was felt to stiffen beneath the massaging fingers and to assume again, after twenty-seven minutes, spontaneous contractions. These contractions were at first irregular, and at one time it was thought that they were going to cease; however, they continued and became more forceful and regular. The character of the response of the galvanometer string, as observed visually, appeared to assume a normal configuration. Two minutes after spontaneous rhythm occurred, there was a rapid, strong regular pulse. Observation of the heart was continued for approximately one-half hour, with the thorax open. Penicillin, 100,000 units dissolved in 10 cc. of procaine hydrochloride, was flushed onto the pericardium. The wound in the chest was then closed with interrupted silk sutures. A plaster boot was applied to the foot. Spontaneous respirations were present and had begun approximately fifteen minutes after the onset of cardiac arrest, while the heart was still being massaged but before it had reverted to a normal rhythm. Spontaneous respiratory effort was amplified by intermittent compression of the breathing bag. During recovery, the patient vomited several times and the trachea had to be cleared by suction. When the patient left the operating room, approximately three and a half hours after the anesthesia had been started, he was semicomatose, restless, vomiting, coughing and breathing spontaneously. He was returned to the ward and placed in an oxygen tent under the supervision of a special nurse, with the hope that the ravages of anoxemia of the brain would not leave a permanent scar.

The electrocardiographic tracing (fig. 3) was studied by Dr. Robert S. Starr, who gave the following interpretation: An electrocardiographic record of this patient was started about twenty minutes after pulsation, heart sounds and respirations had ceased. The tracing was continued, with two interruptions of a few seconds each, while the leads were changed, until a normal heart mechanism was reestablished. Throughout the first two leads the ventricular complexes were absolutely arrhythmic and totally differed from one another in contour. No P waves were identified. This portion of the electrocardiogram was typical of ventricular fibrillation. These curves were at a rate of 365 complexes per minute. Fibrillation ceased during the few seconds occupied by shifting from lead 2 to 3. When the record was resumed, no evidence of cardiac activity was present for a period of five tenths of a second. Then followed a run of ten bizarre, aberrant arrhythmic ventricular contractions, some of which seemed to be preceded by P waves. The heart mechanism then gradually returned to normal, the QRS complexes remaining bizarre and of small amplitude for

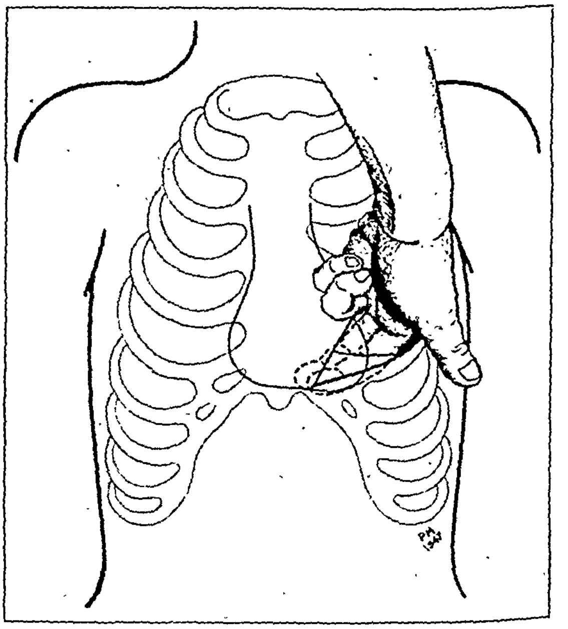

Fig. 2.—Diagram of approach for cardiac massage.

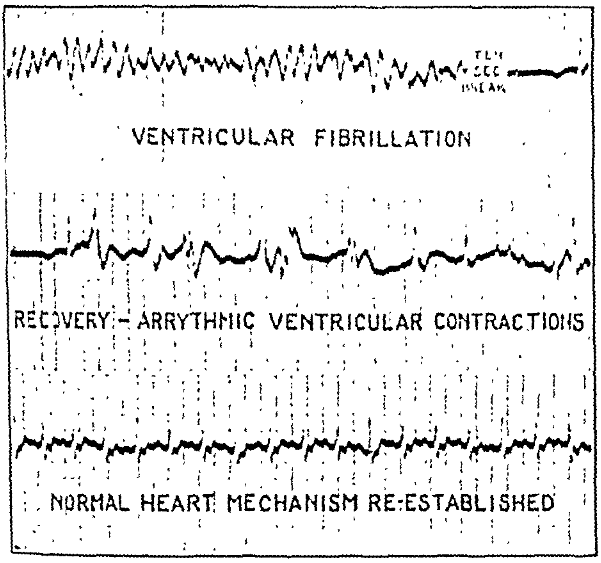
a few seconds. The ST interval remained depressed for a slightly longer period.

The immediate postoperative course was distressing and ominous, because of the effects of cerebral anoxemia. Excerpts from the neurologic notes by Dr. James C. Fox Jr., which follow, summarize the most important aspects of the recovery period: The patient could be aroused for the first time ten hours after operation, and he then spoke a few words. During the first twenty-four hours he remained restless, but lapsed into periods of sleep. His vision was impaired, but he could count fingers accurately. He could give his name. During the second twenty-four hours he became progressively more wakeful and talkative, but was confused. There was evidence of clumsiness of the hands, associated with bilateral astereognosis. Improvement continued, and on the fourth day he was alert, calm, oriented and in good rapport. His span of attention, however, was short, and he tired easily. He was unable to write his name, but could form a few letters. Progress continued, and by the fourteenth postoperative day he was able to write. He could feed and dress himself. He was interested in simple forms of occupational therapy and in comic books (fig. 4). His visual acuity was 20-50, and his visual fields showed no contraction.



TEN SEC BREAK
VENTRICULAR FIBRILLATION
RECOVERY - ARRYTHMIC VENTRICULAR CONTRACTIONS
NORMAL HEART MECHANISM RE-ESTABLISHED

Fig. 3.—Electrodiagrams showing ventricular fibrillation, recovery and final normal rhythm.

The thoracic wound healed cleanly except for a small stitch abscess. The pleural cavity remained free from infection. A small superficial abscess developed in the foot during the second week, in spite of the prophylactic administration of penicillin, but cleared promptly with conservative therapy. During his convalescence two supportive transfusions were given. The hematocrit was never recorded below 32. Several electrocardiographic tracings were all reported as normal. On August 11, the twenty-sixth postoperative day, he was discharged from the hospital to his home, an alert but spoiled child.

After his discharge he continued to improve. He could walk and run without a limp. He returned to school and obtained a score of 108 in the form A Otis Quick Scoring Mental Ability Test. His visual acuity returned to 20-15. On December 20, five months after operation, his mother stated, "He is the same boy we took to the hospital, and the problems we have with him now are the same ones that were present before his injury."

COMMENT

The heart has an inherent capacity to function as a pump, but when sudden circulatory arrest occurs no one can foretell whether a few stimulatory manipulations of the heart through the diaphragm will induce an effective rhythm or whether a prolonged period of artificial circulation by cardiac massage will be necessary. Time is at a premium and must not be squandered. The dead line for complete recovery is three minutes and ten seconds.[13]

If the thorax is open when the heart stops, massage can be quickly and effectively executed. If the abdomen is open when the heart stops and massage through the diaphragm does not produce a palpable radial or carotid pulse, the massage is probably not effective in propelling the circulation and the heart should be securely grasped by actually entering the chest without delay, either through the left side of the diaphragm[7a] or through a new transthoracic incision. When neither cavity is open, a direct anterior intercostal approach, through the left fourth or fifth interspace, should be made. This will allow the index and middle fingers of the left hand to be placed directly against the heart, so that effective intermittent compression of the ventricle against the sternum can be done. The maintenance of adequate respiratory exchange by intermittent compression of the breathing bag containing oxygen is as vital as the cardiac massage. The anesthetist must maintain a clear airway in a closed system, assured, if possible, by the insertion of an endotracheal tube. The pressure applied to the bag should be sufficient to expand the thorax, but must not produce dilatation of the stomach.

When an adequate circulation has been established by manual propulsion of the blood and when anoxemia has been controlled by artificial respiration, the first crisis has been surmounted and there is time to consider the available measures for reestablishing an effective heart beat. The diagnosis of the type of cardiac disorder will determine the further course of treatment.

Fig. 4.—Photograph of the patient, taken eleven days following operation.

13. Weinberger, L. M.; Gibbon, M. H., and Gibbon, J. H., Jr.: Temporary Arrest of the Circulation to the Central Nervous System: Physiologic Effects, Arch. Neurol. & Psychiat. 43: 615-634 (April) 1940.

In cardiac standstill observers [14] describe an absolutely quiet heart, while in ventricular fibrillation aimless ripples can be seen beneath the pericardium. Even though only one previous electrocardiographic tracing of this surgical and anesthetic emergency [15] with recovery has been published, it is apparent that the electrocardiograph is of great diagnostic as well as academic importance, as it alone establishes beyond question the true nature of the cardiac episode.

If it has been determined that the ventricles are in fibrillation, procaine hydrochloride, 5 to 10 cc. of a solution of 1 per cent concentration, should be given intravenously or directly into the heart. With good fortune a brief postundulatory pause will occur, to be followed by effective coordinated ventricular contractions. If defibrillation does not occur, the dose can be repeated or, if the equipment is available, electric stimulation, as outlined and perfected by Beck, may be applied. Epinephrine should be reserved for cardiac standstill and is best given intravenously, into the heart or into the cardiac muscle, in a dose not exceeding 1 cc. of 1 to 1,000 dilution. Epinephrine may be valuable during recovery following restoration of cardiac action to strengthen contraction of the myocardium. It should not be used in the presence of ventricular fibrillation, as it makes a hyperirritable myocardium more irritable and more difficult to control. By the same token, a heart in standstill may be thrown into ventricular fibrillation if the dose of epinephrine is excessive. In the presence of an uncertain diagnosis, procaine hydrochloride is the drug of choice and should be given promptly to facilitate the reestablishment of normal cardiac function. If hemorrhage and shock are complicating factors, blood should be given to assure an adequate cardiac filling.

When coordinated cardiac action has been resumed and the operation completed, the damage of anoxemia must be estimated and emphasis directed at aiding and encouraging the recovery of injured cerebral and cortical tissue. If the period of circulatory arrest was less than three minutes, complete recovery may be expected, but if more than eight minutes, survival is not likely.

In conclusion, it may be said that in the presence of sudden circulatory arrest inaction and indecision will lead to a certain fatality. Just as artificial respiration is mandatory for respiratory failure, so cardiac massage must be quickly and effectively instituted for circulatory arrest and, if necessary, supplemented by the considered and judicious administration of procaine hydrochloride, epinephrine, electric stimulation of the heart, or all three.

SUMMARY

A case of circulatory arrest due to proved ventricular fibrillation of twenty-seven minutes' duration, with complete recovery, is presented. Cardiac massage was employed and procaine hydrochloride administered intravenously to reestablish regular rhythm.

Electrocardiograms, indicating the existence of ventricular fibrillation, a period of transition leading to recovery and the final normal rhythm, are shown.

Suggestions for the handling of similar situations are presented.

179 Allyn Street.

THE BLADDER IN GENITAL PROLAPSE

ARMANDO TRABUCCO, M.D.
Buenos Aires, Argentina

In 1946 I published with E. G. Murray a paper on the morphology of the bladder in cystocele.[1]

The present paper deals with the dependence between the urinary reservoir and the anterior vaginal wall, as well as with the various physiopathologic disturbances of urination following genital prolapse in its different degrees.

The particular forms that the vesical cavity adopts, the modifications of its different diameters, the important changes in the vesical neck and their effect on micturition, and the possibilities of recovery from such urinary complaints will be discussed.

When genital prolapse takes place, the bladder is dragged backward and downward and the so-called cystocele is formed. The organ undergoes decided changes in form which, affecting directly its normal functioning, bring about subsequent alterations in its kinesis and evacuation of urine. Besides, when the lower part of the vesical wall is dragged by prolapse, pronounced alterations in kinesis of the ureters will take place, as the inferior ends of these ducts are the only fixed points holding the vesical trigone. Bearing all this in mind, let us see the results of cystoscopic and roentgenographic examinations.

CYSTOSCOPIC APPEARANCE

Normal Bladder.—Although cystoscopic description of the normal bladder is out of place here, I shall only point out the parts that will suffer changes after genital prolapse.

During cystoscopic examination of the bladder filled with 150 cc. of fluid, the vesical walls, in a normal person, are definitely convex. The air bubble is always seen in the dome; the mucosa is pink and presents a smooth, shining surface. The vesical trigone is symmetrically placed in the median line; it is an equilateral triangle formed by the ureters and the vesical ostium. The interureteric ligament, scarcely marked, enables one to see the whole retrotrigonal wall. The vesical neck, of a triangular shape, must be regular; its posterior lip, larger than the anterior lip, is slightly protruding and motile when the patient starts micturition.

CYSTOSCOPIC APPEARANCE DURING PROLAPSE

First Degree Prolapse.—Vesical changes in prolapse of the first degree may be slight but they are always present, and, although in most patients examined the bladder was almost normal, a careful examination will show alterations appearing in the vesical wall proper, which becomes slightly trabeculated through hypertrophy of the plexiform layer. The air bubble tends to be displaced toward the anterior wall. The vesical trigone begins to undergo some changes caused by the ureter's pulling it, thus destroying its regular outline. The interureteric ligament and the vesical fundus appear more pronounced. The vesical neck also undergoes changes: the posterior lip becomes hypokinetic.

From Alvear Hospital.

Read before the Section on Urology at the Ninety-Sixth Annual Session of the American Medical Association, Atlantic City, N. J., June 13, 1947.

1. Murray, E. G., and Trabucco, A., in Congreso argentino de ginocologia y obstetricia, 194, p. 1398.

In prolapse of the second degree the foregoing modifications gradually becomes more pronounced until, in prolapses of the third degree, one can observe decided modifications in the vesical walls; the trabeculated bladder is the rule; the mucosa presents symptoms of infection, usually of a chronic type; the air bubble appears displaced anteriorly and is sometimes above the anterior lip of the vesical neck; the trigone is markedly modified; it is irregular and hypertrophic; the protruding interureteric ligament bounds an enormous vesical fundus with thick trabeculated walls; the posterior lip of the vesical neck, less marked and immobile, appears elongated in a longitudinal direction and is lower than the anterior lip; the ureteral meatuses which form the angles of the trigone appear as if pulled upward, deformed and open.

ROENTGENOGRAPHIC EXAMINATION

Although cystoscopic examination will show the state of the bladder during genital prolapse, it cannot show clearly the condition of the vesicourethral outline and the deviations of the vesical and urethral diameters from the normal state.

In order to make a comparative study, one should see first the normal bladder filled with opaque substance, in a picture taken with the patient standing in anterior half lateral position, avoiding the large osseous portions of the pelvis and trochanters and with a degree of inclination that will enable one to see the anteroposterior outline of the bladder. To produce contrasts, the bladder was filled with 250 Gm. of 6 per cent sodium iodide.

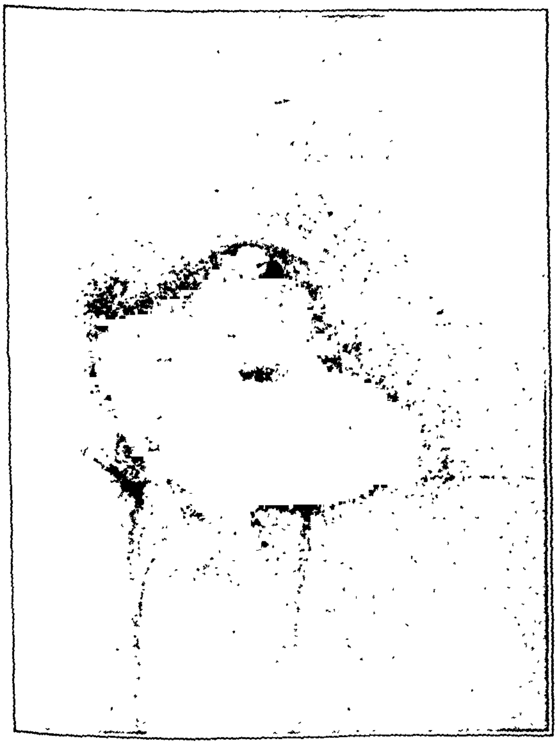

Fig. 1.—Normal bladder, half lateral standing position

Normal Bladder.—A normal cystogram of a woman standing in half lateral position shows the vesical globe of an elliptic regular shape, divided into two equal portions by the urethral axis. The air bubble, which is always found, appears definitely differentiated from the vesical opaque medium; it is located in the upper median portion. The upper border of the bladder is formed by a semicircle, the radius of which is longer than that of the anterior and posterior portions; no deformations are present. The border corresponding to the vesical base is divided into two equal parts by the urethra; it is slightly concave, forming what I have called the anterior and posterior fundus, the latter being more pronounced.

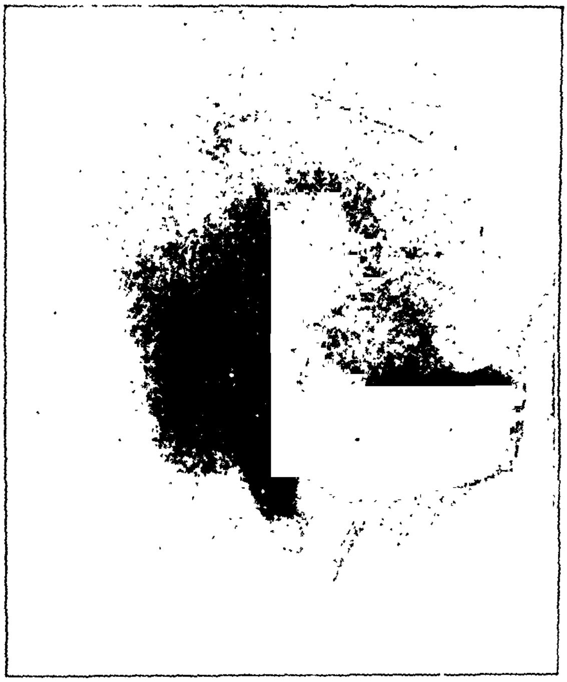

Fig. 2.—Prolapse of first degree, half lateral standing position.

The urethra enters into the bladder perpendicularly to its base and presents a slight anterior concavity; this sign is of the greatest importance when compared to pathologic conditions that will be described later. The vesical neck has a great importance in this study. In order to see it clearly, it is often necessary to reduce the contrast substance or inject through the urethra only 20 cc. In normal persons the vesical neck is clearly distinguished by two lips, anterior and posterior; the anterior lip forms a right or slightly obtuse angle, the sides of which are the urethra and the inferoanterior vesical wall, and the posterior lip forms a right or acute angle the sides of which are the urethra and the vesical trigone. This posterior lip of the neck is always placed slightly above the inferior lip, in relation to an imaginary line crossing this zone horizontally (fig. 1).

ROENTGENOGRAPHIC PICTURE IN FIRST DEGREE PROLAPSE

Cystography, as described, will show that the vesical globe tends to be displaced backward; it is laterally elongated and adopts an ovoid shape with a larger posterior circumference. The air bubble is beginning to be displaced backward.

The urethra penetrates into the anterior part of the lower border of the bladder instead of the median part, as normally; besides, the anterior fundus has become smaller while the posterior fundus has become exca-

GENERAL PRACTITIONERS SESSION

CARE OF THE CANCER PATIENT AFTER HE RETURNS HOME

ALTON OCHSNER, M.D.
New Orleans

Before a patient who has been treated for cancer is discharged from the hospital he should be reassured concerning his condition, because too many persons believe that cancer represents a hopeless condition and that nothing can be done for it, which, of course, is contrary to the facts.

Most patients with cancer who have been seen early and who have had adequate therapy are well, should be reassured of this fact so that they will not fear the persistence of the malignant growth. Even the patient who has had a palliative procedure or in whom a cure was not possible should be reassured about his condition unless there is some definite indication for his being told the true facts.

The person who has been treated for cancer should report back to the attending physician at regular intervals for subsequent observation and examination. In this way, the recurrence of the neoplasm or the development of other manifestations can be detected at a time when something possibly can be done.

Whereas before the definitive therapy of a cancer can be undertaken the patient may have symptoms referable to his lesion, such as pain, interference with normal function of a viscus, such as obstruction of a hollow viscus, or ulceration with its consequent anemia, a patient who has had definitive therapy is relieved of these symptoms. The anemia which previously was a prominent factor and produced severe symptoms no longer exists because, with the removal of the malignant process, there is no longer loss of blood and no further interference with the hemopoietic function so that the patient is able to continue in a fairly normal way. His appetite is better, he is able to enjoy his food and to remain free from symptoms. If, for any reason, there has been resection of the upper part of the digestive tract, such as the mouth, it may be necessary during the preliminary period to feed the patient by tube. In such an instance, it is important to give a diet as nutritious as possible, particularly containing large amounts of proteins, because unless adequate amounts of protein are available, the normal reparative processes are interfered with. The same is true of the patient with a gastrostomy. One is limited, of course, in these instances by the size of the tube which can be inserted either into the esophagus or into the stomach. By means of mixing apparatuses, one can liquefy otherwise solid material and in this way get large amounts of nutritious substances into the digestive tract without much difficulty. In the occasional case in which a tracheotomy has been necessary as a temporary or permanent procedure, it is imperative that some type of suction apparatus be available in order to aspirate secretions from the trachea when they accumulate because of the difficulty which these patients have in expectorating the viscid secretions.

Unless there is some definite contraindication, it is desirable that the patient who has been operated on for malignant disease return to his normal activity as soon as possible. This is of importance not only as regards the healing of his lesion but also because of the beneficial effect on his morale. It is now generally agreed that early ambulation is desirable in the postoperative period because of more rapid reestablishment of normal bodily function but also because of the psychic effect on the patient.

In the patient who has had a resection of the distal colon for malignant disease with the production of an abdominal anus, it is extremely important that a great deal of attention be paid to the colostomy in the early postoperative period. Contrary to what is commonly thought by most laymen and by too many physicians, a colostomy is something not to be feared; with proper care, a person with a colostomy can carry on his normal activities without any difficulty and in no different way from the perfectly normal person. Although a patient who has had a colostomy done as a palliative procedure in which the malignant disease was not resectable does have difficulty with his colostomy in that it is difficult to control the bowel evacuations because of the irritative effect of the malignant lesion, the patient who has had a curative resection of his malignant growth will have no difficulty in controlling his bowels. These patients should be placed on a constipating diet in order to inspissate the feces. They should not be given bags or apparatuses, but should be instructed to take an enema every second or third day in order to evacuate the colon at that time. If this is done, a complete evacuation of the colon is accomplished at one time and in the meantime the patient can go without any fear of discharge of fecal material and without the necessity of wearing a bag or other cumbersome apparatuses. The attention to these few details in a patient who has had an abdominoperineal resection for cancer will do more to rehabilitate that patient to a normal life than probably anything else and will abolish the fear in the minds of other persons who have similar lesions.

Occasionally the patient with cancer in whom resection has not been possible continues to have an ulcerating wound. At times the odor from these ulcerating masses is considerable and extremely disagreeable not only to the patient but also to other persons. In such instances, frequently the changing of the bacterial flora of the ulcerating lesions is possible by changing the mediums. Granulated sugar sprinkled into the ulcerating mass will frequently change the culture medium sufficiently to alter the bacterial flora to eliminate the undesirable odor. The application of chlorophyl ointment to the wound is also frequently of value.

The unfortunate person whose cancer has not been eradicated and who continues to have pain because of the persistence of the lesion can be kept comfortable either by the liberal administration of opiates, which is perfectly justifiable in such a hopeless case, or by a more radical attack on the nerve supply to the lesion. Simple injection of procaine hydrochloride into the involved nerves followed by infiltration with alcohol frequently gives remarkable and astonishing relief. In more persistent cases the intrathecal use of alcohol at times is justified, and in even more persistent and terrible cases cordotomy may be a humanitarian procedure. Although these are only palliative procedures, they are perfectly justifiable in the case of the person who is having otherwise uncontrollable pain.

POSTHOSPITALIZED PATIENT WITH CANCER

Medical and Psychiatric Aspects

WALTER LINCOLN PALMER, M.D.
Chicago

Patients subjected to a presumably curative procedure, usually removal of the cancer, need relatively little care after they leave the hospital; on the other hand, those with incurable cancer usually require a great deal of attention from the physician. I shall not discuss the "cured" group, except to point out that often the morale of these patients is impaired; they require strong reassurance and rehabilitation together with the usual medical procedure such as a diet high in calories and high in protein.

The physician in charge of a patient with inoperable cancer should examine the evidence to make certain, first, that the diagnosis is valid and, second, that curative procedures are really not possible. The diagnosis of cancer is sometimes incorrect, even when it appears to be obvious, and not all apparently inoperable lesions are really inoperable. These points may be emphasized by illustrative cases.

REPORT OF CASES

Case 1.—A man aged 43 years entered the hospital because of extremely severe continuous epigastric pain of six months duration radiating through the body to the back. The referring physican reported that an exploratory laparotomy had disclosed an inoperable carcinoma of the pancreas. The patient was referred for chordotomy to relieve the intractable pain. While arranging for the operation, it was noted that the vomitus consisted chiefly of large amounts of watery, highly acid gastric secretion. Further study disclosed roentgenologic evidence of an ulcer of the posterior wall of the duodenum. When the patient was placed on appropriate antacid management the pain disappeared. Seven years have now passed; the patient is alive and well. The error here was that of relying on gross findings at operation; there was no biopsy; further clinical study or perhaps a more careful examination at the time of the exploratory laparotomy would have disclosed the duodenal ulcer and thus prevented the near tragic and erroneous diagnosis of inoperable pancreatic neoplasm.

Case 2.—A man aged 48 years was subjected to operation in May 1942 for cancer of the rectosigmoid. The patient was a poor risk because of an old myocardial infarction. At operation two metastases were found in the liver; consequently, a colostomy was performed and no attempt made to remove the primary lesion. Two and one-half years later, the patient was again submitted to laparotomy; the liver was perfectly normal; there were no regional or distant metastases; the tumor was removed. There has been no evidence of recurrent neoplasm in the subsequent three years. The error in this instance consisted in failure to make a biopsy of the presumed hepatic metastases at the first operation and in the consequent assumption that the primary lesion was inoperable.

Case 3.—Brunschwig[1] has shown that many apparently inoperable cancers are, in fact, operable. A patient aged 55 years entered the hospital with the picture of complete extrahepatic biliary obstruction. The presumptive diagnosis was carcinoma of the head of the pancreas, a lesion considered, at that time, to be inoperable. However, the patient was subjected to laparotomy; Dr. Brunschwig found a primary carcinoma of the ampulla of Vater and resected the tumor; recovery was uneventful. Three years later the patient returned with abdominal pain, diarrhea and loss of weight; a mass was palpated in the right side of the abdomen; roentgenograms disclosed a filling defect in the ascending colon. At operation, Dr. Brunschwig found a primary carcinoma of the ascending colon; there were no metastases; resection was again followed by uneventful recovery. The patient is still alive and well, five years after the first operation and two years after the second.

COMMENT

Unfortunately, however, the diagnosis of inoperable neoplasm is usually correct and the problem is purely that of palliation. The standard hygienic procedures are diet, rest and exercise, all of which should be prescribed by judgment rather than by rule. Ordinarily a diet high in calories and high in protein is desirable; it must be cooked well; moreover, it should be served attractively and cheerfully. Rest and exercise are of both physiologic and psychologic value; they should be advised in graduated amounts as tolerated by the patient.

The chemotherapy of malignant disease seems to be entering a new era; its eventual complete success will be hoped for, but, at the present time, that goal seems remote. Arsenic has been used for many years in the treatment of leukemia, often wth dramatic palliative results.[2] Certain aleukemic states, reticulum cell sarcomas or lymphoblastomas, may likewise respond in a most gratifying manner with a clinical remission and objective evidence of regression, such as a decrease in the size of an enlarged spleen or liver. The more common inoperable cancers, however, seem at present to be completely unaffected by arsenic or by any of the chemotherapeutic measures used thus far. The nitrogen mustards[3] have proved helpful in Hodgkin's disease and in other neoplasms of the lymphatic system chiefly as an adjunct to radiation therapy. In certain cancers, notably carcinoma of the prostate and of the breast, hormonal therapy has produced spectacular results, although it has not replaced surgical removal. The estrogens, such as diethylstilbestrol, may be used in advanced prostatic cancer, with or without orchiectomy. There can be no doubt of their palliative effect on the primary tumor and also on the metastatic lesions, particularly those in the skeleton. Castration, be it by surgery, radiation or hormones, inhibits to a variable degree and for a variable period the growth of these specific malignant cells. Huggins,[4] in an analysis of the five year results of orchiectomy, reported that remissions of varying length occurred in 18 of 20 patients with disseminated prostatic cancer; after five years 1 patient was alive with slowly advancing cancer; in 4 there was no clinical or laboratory evidence of cancer. Similarly, the skeletal metastases of mammary cancer may be influenced by large doses of testosterone propionate.[5] However, it is not yet possible to make a final appraisal of the effectiveness of hormonal therapy.

The question is often asked as to which drugs should be used for the relief of pain in incurable cancer. Here again no arbitrary answer can be given, for so much depends on the patient, the family, the physician and the total situation. Generally speaking, the wise physician will choose the drugs needed to give relief. The barbiturates do not ease pain; they do reduce nervous tension and they bring greatly needed sleep and rest. Chloral hydrate is used less frequently, but may be helpful. In some circumstances as the inevitable end approaches, these drugs alone may enable the patient to sleep life peacefully away. Usually, however, it will be necessary to combine the hypnotic drugs with opiates; in fact, if opiates are used in adequate amounts, other medications may often be discarded. Codein may suffice for a few days or weeks, but usually it becomes ineffective. Morphine in doses of $\frac{1}{8}$ to $\frac{1}{4}$ grain (8 to 15 mg.) may be given as frequently as needed; addiction is not to be feared. The smoking of opium is foreign to Western culture, but in this particular situation it might prove of as great value for us as it has for the Chinese. The various substitutes for morphine, such as *meperidine hydrochloride, are rather effective.* The physician should use in adequate amounts the drugs with which he is familiar.

Thus far I have dealt with the more tangible phases of the care of the patient with incurable cancer, but perhaps not with the more important ones, the attitude of the patient and of his family to the disease and its ultimate inevitable outcome. Usually the first questions to arise are what the patient should be told and what should be said to the family. Opinions differ with regard to these questions; doctors differ; situations differ and change. Certainly the patient should be told enough to induce him to carry out the treatment indicated, to enable him to make the proper decisions and to dispose of essential business matters. I have rarely considered it necessary or wise to tell a patient bluntly that he has a cancer. The connotations of the word "cancer" are, as a rule, much worse for the layman than for the physician; consequently, softer and less final words such as ulcer, growth and tumor may often be used to advantage. If the patient then persists in his questions and insists on knowing whether the lesion is "malignant," one may decide to give the direct affirmative answer, qualified, perhaps, with the explanation that malignant lesions vary greatly in their rate of growth and that some malignant lesions are relatively benign. Such statements are, in fact, the truth, and they have the further advantage that they leave with the patient a ray of hope. It is cruel to destroy all hope; furthermore, the physician's diagnosis and prognosis may be wrong! The physician's task, after all, in this particular disease is to ease both the physical and the mental suffering of the patient as much as possible.

If a cancer is removed at operation, little is gained by gleeful statements to that effect; softer words with reassuring instructions and smiles are more helpful. If the cancer proves inoperable, then appropriate explanations are in order, accompanied again by instructions for the further management. Of course, the family, or at least, some responsible member, should be told frankly of the situation and should be kept informed as developments arise not only for the protection of the physician, but, more particularly, in order that the most satisfactory environment for the care of the patient may be created.

In theory, at least, the religious views of the patient are of no concern to the physician; in practice, however, the physician, consciously or unconsciously, takes them into consideration; they help to determine the attitude of the patient. This is scarcely the appropriate time or place to discuss questions of religious faith, but there are enormous differences in the way in which people face the imminence of death; some accept it with courage and fortitude, with a transcendent faith and serenity of spirit; others face it with fear and terror; some refuse to face it at all. The physician cannot alter the patient's basic reaction, but he should understand it. *By attitude, rather than by word, he should provide* as much strength and fortitude as possible. The physician is not called on to assume primary responsibility in spiritual matters; these are the private concerns of the patient, his family and the minister, priest or rabbi; every family physician knows, nevertheless, that in such times of crisis his role is not a minor one. The splendid monograph by the late Richard Cabot and his minister friend, *Russell Dicks,*[6] on "The Art of Ministering to the Sick" can be read with great profit, for it provides many insights and gives a better understanding of the differing reactions of patients to illness and approaching death.

Death, of course, is inescapable; it comes in various ways. Most of us, perhaps, would prefer it to come suddenly, silently, painlessly, when we are totally unaware of its approach. You will recall, however, than Hans Zinsser felt differently, for, as leukemia ran its course, he "felt increasingly grateful for the fact that death was coming to him with due warning, and gradually." In his last sonnet he wrote "Now is death merciful.—How good that 'ere the winter comes, I die!"[7]

Francis Peabody, in his middle forties, at the very fruition of his medical career, accepted the tragedy of an advanced gastric cancer with a similar transcendant tranquillity of spirit. He met this desperate situation "without defiance, without dismay, without show of regret and . . . without resignation. . . . It was accepted quietly, as a thing all in the day's work, handsomely, as a gentleman should accept a challenge."[8] Zinsser and Peabody had both achieved a fulness of life; the flower of their spirits had blossomed into full bloom; death held no terror for them. At an earlier age or under different circumstances, it might have been otherwise. You will recall Fitz-Greene Halleck's poem[9]:

> Come to the bridal chamber, Death,
> 　　Come to the mother's, when she feels
> For the first time her first-born's breath! . . .
> Come when the heart beats high and warm,
> 　　With banquet-song, and dance, and wine!
> And thou art terrible!—the tear,
> The groan, the kneel, the pall, the bier,
> And all we know, or dream, or fear
> 　　Of agony are thine.

And so the physician as a fellow human being and as a friend must understand the significance of the approaching tragedy to each patient and to the family. To the physician is given the privilege of sharing in the joys and the sorrows of life, in its heartaches, and in the sacred sublime hours when, with or without the support of family, friends and clergy, the patient enters on the final experience.

It would seem foolish to speak of the psychotherapy of cancer, as if one might influence a neoplasm by any such procedure, but it is not foolish to speak of the psychotherapy of the patient with cancer. Psychotherapy, using the term in its broadest sense, is inevitably present in the treatment of all diseases, whether recognized or not; perhaps, indeed, it is most effective when not recognized and hence given unconsciously. The ability of some patients to deny or blot out pain, to refuse to admit to themselves or to any one else their progressive decline, is an amazing phenomenon. It is seen not infrequently in the practice of medicine; it is utilized by quacks and faith healers; it sometimes misleads physicians, for patients may gain, temporarily, in weight, strength and well-being in spite of the steady advance of the disease. In recent months I have seen a woman bedridden from innumerable osseous metastases of a cancer of the breast rehabilitated after the injection of a "new serum" given by a faithful nurse. The patient was able to resume for several months an active almost normal life in spite of the fact that roentgenograms taken from time to time disclosed rapid progression of the tumor throughout the skeleton instead of the regression anticipated from the excellent clinical condition. The attending physician attributed the symptomatic improvement to the splendid nursing care and the psychotherapy of the "new serum" administered enthusiastically.

This case illustrates the important fact that the practitioner must take an active interest in the progress of the patient; the physician must see the patient frequently at home or in the office; various therapeutic and palliative procedures should be tried, sympathetically, if not enthusiastically, for, while they may not have any value from a scientific point of view, their suggestive and psychotherapeutic value may be very great.

These brief remarks on the medical and psychiatric care of the posthospitalized patient with cancer may be concluded with a quotation from Francis Peabody's paper on "The Care of the Patient,"[10] written as he gave ground steadily to his own neoplasm, but containing no reference to it. Every physician would do well to bear constantly in mind and, perhaps, especially so when dealing with patients with cancer, the concluding two sentences of this delightful penetrating essay:

> Time, sympathy and understanding must be lavishly dispensed, but the reward is to be found in the personal bond which forms the greatest satisfaction of the practice of medicine. One of the essential qualities of the clinician is interest in humanity, for the secret in the care of the patient is in caring for the patient.

WHAT TO DO FOR THE CANCER PATIENT WHEN HE RETURNS HOME

The Role of the Radiologist

EUGENE P. PENDERGRASS, M.D.
Philadelphia

The problem of what to do for the patient with cancer when he returns home as it concerns the radiologist may be divided into two categories: (1) diagnostic procedures and (2) palliative therapeutic procedures.

DIAGNOSTIC PROCEDURES

The symptoms that occur often in many patients who have had operations for removal of a malignant tumor include tightness of the chest, dyspnea and cough, rapid pulse, pain in the chest, lumbago, pain in any part of the body, headache, diplopia, dimness of vision, ringing in the ears, unsteady gait, loss of appetite, constipation, ascites and fever. It should be emphasized that multiple cancers are not uncommon and that one should be on the alert for such a possibility.

The roentgen examination of the chest is the best method of demonstrating metastatic disease of the lungs, mediastinum and pleura. Metastatic cancer may produce cough, dyspnea, pain in the chest, tight feeling of constriction in the lower part of the chest and a rapid pulse. *Carcinoma of the breast is one of the most* frequent causes of metastasis to the thoracic structures. Many times the patient thinks that she has a cold which will not clear up, and in such instances, if one has a high index of suspicion, the true nature of the condition can be demonstrated early by a roentgen examination of the chest. Metastasis to the lungs does not always produce a cough.

Lumbago and pain in the hip, shoulder and elsewhere are often due to metastasis to bone from various organs, such as carcinoma of the breast to prostate, or any of the lymphoblastomas. It sometimes is possible to make a clinical diagnosis before the roentgen diagnosis will demonstrate any abnormality. Thus, a roentgen examination of bones which shows no evidence of metastasis should not be regarded as negative unless there is some other explanation for the pain. It is well known by radiologists that unless the cortex of the bone is involved the lesion may not be detected unless one is able to compare roentgenograms made before symptoms with those of an examination after pain has developed.

Lumbago or unexplained fever is oftentimes due to metastases to retroperitoneal lymph nodes. *Metastasis to renal lymph nodes* from a testicular tumor often causes lumbago or lumbar pain referred to the groin and down the leg. Unexplained fever may be due to enlargement of retroperitoneal lymph nodes in Hodgkin's disease and in malignant lymphomas. Lumbago may be due to blockage of the ureters from carcinoma of the cervix which has invaded the broad ligaments. Urographic roentgen examination and roentgenograms of the abdomen oftentimes will provide the clues as to what is producing the symptoms.

Headache, diplopia, dimness of vision, ringing in the ears and unsteady gait are symptoms that are often

produced by metastases from carcinoma of the lung and breast. In many hospitals it is a routine procedure for the neurosurgeons to request a roentgen examination of the chest, because they have learned to exclude metastasis as a cause of the neurologic phenomena before operating on the patient for a brain tumor. My associates and I have seen patients with symptoms referable entirely to the eyes that have been produced by metastatic carcinoma from the breast.

Loss of weight, loss of appetite, constipation and ascites are often due to metastases to the liver or other abdominal organs or structures. The symptoms may be acute or may be insidious. If the index of suspicion is high a correct diagnosis will generally be made or suspected of a condition which otherwise might go undiagnosed. The roentgen examination of the abdomen and of the gastrointestinal tract oftentimes will aid one in arriving at a correct diagnosis.

One of the most neglected fields in radiology is the follow-up examination after major surgical procedures. This is particularly true in gastric and colon operations, surgery of the lungs, surgery of bone and neurosurgical procedures on the head and spine.

We believe that every patient who has an operation for removal of a part, or for reconstruction, should have a follow-up roentgen examination. Such studies provide a base line for diagnosis should the patient subsequently show symptoms and have a roentgen examination.

PALLIATIVE THERAPEUTIC PROCEDURES

Radiation therapy like roentgen diagnosis covers such a large field that it is impossible to do otherwise than mention a few conditions that respond well to radiation and provide some degree of palliation.

Pain due to metastasis to bone may in many instances be relieved by irradiation. When destruction of bone is present, new bone forms after therapy and the symptoms disappear. Even when a pathologic fracture develops, the bone heals after irradiation in most cases.

Pain due to metastases to the spinal cord does not respond well to irradiation. Some other procedure such as surgery is more efficacious. On the other hand, if the pain is relieved by surgical measures, irradiation does provide palliation and may have a distinct retarding effect on the growth.

Cough and dyspnea and pain in the chest may oftentimes be relieved by radiation, even small doses.

Inoperable metastases and recurrences in many instances are helped and occasionally cured by appropriate irradiation.

It may be well to discuss briefly my views concerning the role of irradiation in the treatment of carcinoma of the breast.

We do not recommend preoperative irradiation in operable lesions. If the breast is found to be operable, we do not believe that it is necessary to give radiation over the operative field. One may give irradiation over the supraclavicular region in such patients as prophylactic procedure as recommended by Portmann.[1]

We do recommend irradiation in inoperable carcinoma of the breast, and the criteria for operability that we adhere to are those recommended by Haagensen and Stout.[2]

Only inoperable recurrences or metastases should be treated by irradiation.

Ovarian irradiation has been demonstrated to be a palliative procedure. It may be given immediately after the radical operation on the breast or it may be deferred until recurrences or metastases develop and or until after other measures have failed. Most patients respond for a short time, and a number will be helped for one to three years.

Every physician who cares for a patient with cancer is obligated to teach the patient what symptoms to look for and how to make a self examination. Our experience has led me to believe that patients can assume an important role in the early recognition of early metastasis, even when they are not told the true nature of their disease.

The relationship of sex hormones and neoplasms has been the stimulus for a great deal of investigation in recent years. The antiandrogenic treatment of cancer of the prostate was introduced by Huggins and Hodges in 1941[3] and has proved to have definite practical value. Cancer of the prostate is stimulated by androgens and is inhibited by either excision of both testes or by administration of the female sex hormone.

Some of the benefits observed include increased appetite, relief of pain, gain in weight, loss of the anemia, reduction in size of the primary tumor, healing of bone metastases and disappearance of soft tissue metastases. The results are not uniformly successful, but remissions may last from two to five years.

Many clinicians interested in cancer of the breast have employed the male sex hormone in the treatment of extensive breast cancer with bone metastases. Early efforts with small doses were not so valuable,[4] but recently larger doses have been employed with greater benefit.[5] The palliative response included symptomatic loss of pain and increased sense of well-being. In many, the bone metastases heal and occasionally the primary tumor is reduced in size. There still is much work to be done in this field, but the results thus far have been encouraging.

There are many other phases of the problem concerning the role of the radiologist in the care of the cancer patient. Those mentioned serve to illustrate how he can be most helpful if his efforts are integrated with those of the family physician.

Myasthenia Gravis.—Up to about 1935 the mortality was between 50 and 75 per cent, so its name, "grave myasthenia," was indeed justified. I have estimated that in one hospital where I am working, over a period of thirty years prior to 1935 we had only 30 cases, one a year, and that half of those cases died in the hospital and another half died within a year after leaving the hospital. This was indeed a fatal disease. The mortality from the disease at the present time, however, is probably less than 10 per cent, so that we have reduced the death rate from roughly 50 to 75 per cent down to less than 10 per cent. . . . All our patients take the medicine orally in the form of prostigmine bromide, the only tablet made for oral medication. There are 15 mg. of neostigmine bromide in each tablet. Under certain conditions we may supplement the oral dosage with subcutaneous injection, but that is rarely done, and not more than 2 or 3 per cent of my patients take the drug subcutaneously. They are all adjusted to oral neostigmine bromide.—Viets, Henry R., M.D., *Postgraduate Medicine,* July 1948.

NUTRITIONAL PROBLEMS OF ADOLESCENCE

JOSEPH A. JOHNSTON, M.D.
Pediatrician-in-Chief, Henry Ford Hospital
Detroit

Most of the "problems" which bring the average parent of the adolescent to the physician are problems only to the extent that the parent fails to appreciate what normally should be expected at this age, and how wide is the time range within which may take place the events terminating skeletal growth and the attainment of sexual maturity. The mother who is concerned because her daughter is larger or smaller than her companions of the same age seems unaware that chronologic age is no measure at all of the events of this period, but that now there is being forced on us an assessment of normal progress in terms of physiologic age; that each person will have his own inherited time schedule and that his progress in growth must be measured against the yardstick of his sexual maturing. An attempt to compare the growth progress of a schoolroom of 13 year old girls will bring this point home better than anything which I can say. It will be found that their gains in height for the previous year have varied from 1 inch to 4 (2.5 to 10.2 cm.), and in weight from 6 to 30 pounds (2.7 to 13.6 Kg.), and this without there being an abnormal child in the group. It will be noted that about two thirds of the group have just menstruated for the first time, and that half of the remainder will be one, two or three years away from achieving this function, while in the other half of the remainder it will be an equal number of years in the background. When comparisons of growth are limited to girls in the same physiologic age group, seemingly hopeless discrepancies disappear and predictions become possible within relatively narrow ranges.

Such growth problems as do exist, and it is true that they come into bolder relief at this age than at other periods in the growth span, relate to the fact that growth is extremely unstable at this time, the rate actually doubling just preceding and halving just following the menarche in girls, a similar pattern being seen in boys about two years later and being measurable against their attainment of sexual maturity within just as wide a range as the girls. This correlation of the rate of growth with sexual maturity rather than chronologic age is well brought out by Boas[1] and by Shuttleworth,[2] and a recognition of it is fundamental to an understanding of the adolescent.

The actual time of occurrence of the first menstrual period is the source of much needless anxiety, which can be allayed when a mother is made to realize that while 13 is the average for this incident, the range is from 10 to 16. She needs likewise to be reminded that the only predictable thing about the menstrual cycle of the adolescent is its unpredictability for the first two years and that true abnormalities will reflect more often physical and emotional abnormalities of the whole child than those that relate specifically to the sex hormones.

The rate of metabolism at this period shows the same instability as does the rate of growth, a tendency for elevated rates to precede and depressed rates to follow the point of maximum growth. As a by-product of this, hyperthyroidism, rare in earlier childhood, becomes relatively common in the prepuberty spurt of growth, and depressions of metabolism reaching pathologic levels are frequent in the years that immediately follow puberty.

It might be predicted from a study[3] of growth curves that the assimilation from the diet and the storage within the tissues of those food elements that enter into the making of muscle and skeletal tissues—for example, *nitrogen in muscle and calcium in bone*—would show changes that paralleled the growth rates, as indeed they do. With diet unchanged, retentions of these items have been shown to be halved in the period following puberty in contrast to the period that preceded it, and, further, the requirement for these items is satisfied within much narrower ranges than at those periods of growth that are more stable. During a year when a child is adding 3 inches (7.6 cm.) to his height, his calcium requirement will be satisfied with *no less than* the amount that *occurs in* a quart of milk, and his need for vitamin D is probably twice as great as at any other time in life with the possible exception of the middle of the first year. His protein needs likewise are higher than they will ever again be in life, and the attainment of an optimal storage of nitrogen in his tissues and of a normal metabolism will demand about three times as much as that required in adult life. It is true that when such demands are not met equilibrium is reached at a lower level, but only at the expense of a fall in basal metabolism. Beyond a certain point this will result in a failure to achieve sexual maturity.

The protein and calcium needs of the adolescent will be covered when the diet includes the items in the accompanying list:

	Protein, Gm.	Calcium, Gm.
1 quart milk	28.8	1.152
1 egg	6.0	0.033
Cereal, 1 serving, and bread, 3 slices	13.0	0.067
Meat, fish or cheese, 2 large servings	46.0	0.318
Simple dessert, 1 serving containing egg and milk	3.5	0.102
Soup, 1 serving containing milk	2.4	0.020
Vitamin D—800 Units		

The protein in this diet constitutes 15 per cent of a calorically adequate diet. The total calories can be estimated within a narrow range as approximately twice the basal calories as predicted on a Wetzel grid. This method of calculation is actually practiced only on specifically ordered diets such as those for the person with diabetes; in the average normal youngster, we found in the study[4] from which this figure was derived that instinct was a reliable guide to this amount and that a mother's fear that "he would take too much meat" was unjustified. When amounts greater than this were offered, not only was retention of nitrogen not usually increased, but there was prompt refusal and, in some instances, evidence of protein intoxication.

Read in a symposium on the Treatment of Pathologic Disturbances of Adolescence at the interim meeting of the American Medical Association, Cleveland, Jan. 7, 1948.

If for any reason milk is not taken, the calcium content of a quart, something over a gram, can be supplied otherwise.

The amount of vitamin D recommended is higher than that usually quoted, but the figure is based on calcium retentions reported elsewhere.[5]

OBESITY

The facts that the average obese adolescent is above average height, shows advanced bone age and is in the advanced group intellectually, though retarded in his social and emotional maturation, are all sound arguments advanced by Bruch[6] against attributing the excess weight to thyroid deficiency. The use of surface area standards in the calculation of the basal metabolic rate introduces an error in the case of the obese child of the magnitude of 20 per cent; the use of a standard based on height, or the Wetzel grid, will provide estimates that fit the clinical picture more accurately; by such standards these children are shown to have a slightly elevated metabolism. The use of thyroid in their management is definitely contraindicated; as much loss of mineral and nitrogen can be effected by elevating the metabolic rate to abnormally high levels as results when the other extreme exists, hypothyroidism. The management of the problem of the obese child includes more than the attempt to limit his caloric intake; it involves an assessment of his emotional and social difficulties and the frank facing of the too frequently found overdependent relationship between parent and child.

1,400 Calories, 20 Per Cent Protein

	Calories
Breakfast	
Tomato juice, one 8 ounce glass	36
Milk, skimmed, one 8 ounce glass	138
Bread (whole wheat, rye, graham, cracked wheat), 1 slice	72
Butter, ½ square	40
Egg, one, or a hamburger or small serving of lean meat	75
Lunch	
Lean meat or fish, any kind, 1 average serving or 2 eggs	172
Vegetables, 3%, any amount	18
Vegetables, 10%, ½ cup	46
Bread, ½ slice	36
Milk, 1 glass	138
Butter, ½ square	40
Fruit, fresh or canned without sugar, 7% to 10%, ½ cup	40
Dinner	
Lean meat or fish, 2 eggs, or average serving cottage cheese	102
Vegetables, 3%, any amount	18
Vegetables, 6%, ½ cup	36
Bread, ½ slice	36
Milk, 1 glass	138
Butter, ½ square	40
Fruit, fresh or canned without sugar, ¾ cup 7% to 10% or ½ cup 15%	60
Mid-afternoon	
Milk, skimmed, 1 glass	138

This diet should be supplemented with vitamin D such as one A.B.D. capsule or 5 drops of percomorph liver oil or a halibut oil with viosterol capsule.

The accompanying reducing diet for the obese child recognizes the need for a high intake of protein, calcium and vitamin D at this period, and stresses the use of protein at the morning meal as a means of allaying hunger for longer periods than would carbohydrate without effecting a corresponding increase in weight.

In the case of obese boys, one of the commonest causes of concern has to do with seemingly infantile genitalia. Bruch[6] concluded from her study on this point that "there are no indications to support the common belief of sexual retardation in obese boys. One may expect that there are a few obese children who do not reach this stage (pubescence of Schonfield); yet they seem to be rare, and they would still fall within the normal range." Actually the size of the penis in the obese boy is deceptive because it is obscured in a pad of pubic fat. The use of sex hormones to influence development at this age is unjustified.

EPIPHYSIOLYSIS

Slipping of the upper femoral epiphysis is largely a problem of the period of accelerated growth, the average age of occurrence in the girl being 12, and the boy, 14.[7] It is likewise a problem to a large extent of the obese child, and the possibility of its occurrence is an added reason for dealing vigorously with that condition before puberty sets in. There is no general agreement on its etiology, but in a study of 5 of these patients we found diminished retention of calcium. Since the studies were done after nailing, the poor balances may well have been referable to the surgical procedure, but their prompt correction by the use of vitamin D differs from the experience of Howard,[8] whose calcium losses in cases of fracture were not so influenced. I feel that observation is added support for the need for vitamin D at this age period, as might be anticipated from the increased rate of growth.

THE ADOLESCENT AND TUBERCULOSIS

The abrupt increase in the incidence of the adult or reinfection type of tuberculosis in the adolescent has long been associated in the physician's mind with some change which lowered resistance at this age. That the lesions found at this time represent endogenous exacerbations of primary foci would seem to be borne out by the experience in Detroit in which 1,100[9] children, wards of the Society of St. Vincent de Paul, were followed for varying periods up to twenty years after their detection as reactors and their removal from their sources of infection to rural foster homes. Two thirds of the 29 reinfections detected over this period occurred in girls, the majority between the ages of 11 and 17. Metabolic observations carried out after the detection of the lesion, and practically all were discovered in the minimal stage, suggested from the magnitude of the storages of nitrogen that deficits had existed which were now being made up with an optimal diet and rest. The role of the onset of puberty itself in creating such deficits was studied and the depressed retentions of nitrogen and calcium noted at the menarche were felt to contribute to the reactivation of the lesion, and to its spread when the menarche followed the first appearance of the adult type lesion. The observations lend further support to the need for supplying liberally the increased needs for protein, calcium and vitamin D of this period of accelerated growth.

MENSTRUAL IRREGULARITIES IN ADOLESCENCE

After dismissal of a large number of complaints regarding menstruation as due to a failure to appreciate that, while the average onset of menses is 13, the range is from 10 to 17, and that the establishment of a regular rhythmic cycle is a matter of many months—in one study, twenty-six—there remains a group whose basis can roughly be grouped into the following categories: nutritional, emotional, hormonal and organic defect.

The obese girl and the malnourished share equally in having a disordered menstrual cycle. In both types thyroid has been unwisely employed. Its mistaken use in the obese child has probably resulted, as pointed out elsewhere, from the misleading information gained from the determination of the basal metabolic rate, when this is referred to standards based on the surface area. Malnutrition of any significant degree, not the result of hyperthyroidism or infection, will cause a fall in the metabolic rate; in neither instance is the use of thyroid indicated; the obese child needs dietary restriction, and the supplying of an adequate diet to the undernourished child can cause a rise to a normal rate in two weeks.

Both of these situations may have their basis in emotional difficulties, the obese child using food as a solace for social inadequacies, and the malnourished teen-ager not infrequently developing a state approaching anorexia nervosa when confronted with an inability to keep pace with a school schedule beyond her intellectual capacity.

About one fourth of a group of 50 high school students who complained of menstrual irregularity required thyroid as judged by clinical signs and symptoms, a slow pulse, small pulse pressure, lowered metabolic rate and fatigue, and pallor. Rarely was it necessary to use more than ½ grain (30 mg.). It cannot be stressed too often that the anabolic effects of this hormone become catabolic when amounts are used that elevate the metabolic rate above normal.

Gynecologic consultation in this group should not be too long delayed. Psychic trauma incidental to the examination is not lightly to be dismissed, and the experienced gynecologist has in our experience explored the possibilities mentioned before resorting to it. Nevertheless, a failure to employ adequate examination would have resulted in this series in missing organic lesions in 6 cases—1 of adenomyoma, 2 of ovarian cysts and 2 of hypertrophy and hyperplasia of the endometrium; there was a single instance of primary amenorrhea.

SUMMARY

Adolescence is set apart from the other periods of growth by varying rates of speed, changes in metabolism and the maturation of the sex hormones. Many of its problems can be resolved when the nutritional requirements are met that fulfil these varying needs. More of the problems cease to exist when due account is taken of the wide range of normal of the events of the period.

PSYCHIATRIC PROBLEMS OF ADOLESCENCE

GEORGE J. MOHR, M.D.
Chicago

Commonly encountered problems relating to the emotional and social development of the adolescent will be discussed in this paper. For many young persons, the adolescent period is one in which a relative disequilibrium, physiologic and psychologic, must be coped with. The familiar physical changes of puberty usher in a period in which the relative stability of the prepubescent period is disrupted. Physical growth and development, shift and change in endocrine balance, accompanying change in social and educational relationships conspire to impose a difficult task of adjustment on the adolescent. I shall endeavor to review some of the chief areas in which reactions characteristic for or emphasized by the adolescent are encountered.

PHYSICAL DISABILITY

With respect to problems of physical health, the adolescent is in a vulnerable position. He has little tolerance for the threat of illness or disability; this is particularly true for the boys. Physical disability of any sort is reacted to as a tremendous threat to prestige and in the competitive relationship that characterizes the attitude of the adolescent. Adolescents have a great capacity to deny the existence of any incapacity, since the existence of such provokes deep anxiety. An adolescent boy had required a number of operations on his foot to correct a congenital deformity, had to wear a brace to counteract a tendency toward serious spinal curvature and had an undescended testicle that failed to respond to efforts to effect descent. He devoted his major energy toward denial of his difficulties. One can completely sympathize with his sensitivity and eventual refusal to wear a brace, if there was any chance that this would be discovered by his school friends. He spent endless time and energy in calisthenics and exercise and succeeded in developing a most muscular physique. His emphasis in the direction of physical development was so great that he seemed to have little energy to invest in his academic effort and, though of good intelligence, throughout his high school years has remained on the verge of failure. In his overdetermined zeal to secure himself a robust physique, he has lost sight of the important role that his other capacities play in determining his life situation.

As opposed to the reaction just described, not uncommonly the reverse defensive attitude is encountered. The adolescent who feels himself at a disadvantage on the physical score may stake everything on gaining status through intellectual achievement, perhaps isolate himself as the "grind," but in any event conceive of himself as the intellectual. This fundamental attitude toward himself really includes a great depreciation of his own physical powers. While the emphasis on intellectual achievement may be desirable in itself, particularly if the young person concerned has the capacity to implement his own demands for achievement, the concomitant self depreciation on the physical side tends to maintain an underlying state of anxiety and mistrust of self that interferes with normal adjustment in social and personal relationships.

Like younger children, the adolescent can tolerate no sense of difference between himself and his com-

---

Read in a symposium on the Treatment of Pathologic Disturbances of Adolescence at the interim meeting of the American Medical Association, Cleveland, Jan. 7, 1948.

rades. Daniels[1] reported the difficulties in management of an adolescent diabetic patient, for whom being left out of group games proved a deep embarrassment and being unable to have an occasional snack with his friends a prime deprivation. To the adolescent, the cure is certainly worse than the disease.

SOMATIC DISTURBANCE

Not only does the adolescent react strongly to physical disability or illness to which he may be subjected, but, conversely, he may manifest mild to extreme somatic disturbance in his effort to cope with the emotionally significant problems characteristic for the adolescent. Disturbance of appetite, common in early childhood, is a not infrequent symptom during adolescence. The problems range from those of the adolescent girl who remains too fat to be attractive (she is the subject of a popular song now being heard daily over the radio) to those of the sufferer with so-called anorexia nervosa, whose life is threatened by inability to eat and retain food. In these adolescents, one is dealing with conflict situations already laid down in childhood experience, but with intensification under the influence of pubertal changes and hormonal stimulus. I wish to comment on some of the psychologic and psychiatric problems involved. The physiologic changes of puberty coincide with changes in external personal relationships involving separation from parental protection, and the impending adjustments of adult social and sexual life.

Some boys and girls tend to overeat and gain weight rapidly with the onset of puberty. I am not talking about the healthy appetite of the energetic boy who eats "like a horse" and expends an enormous amount of energy in active sports and other energetic adolescent pursuits. He does not become obese and socially withdrawn, as does the "fat" boy or girl here referred to. Here one is dealing with the adolescent who is basically anxiety ridden and feels incompetent to enter into the more demanding relationships of adult life. Case studies make clear that in some adolescents overeating occurs as a regressive reaction when heterosexual strivings undergo repression. Such a person reverts to an essentially dependent orientation, expressed in a retreat to oral and receptive possibilities for gratification that are normally dominant only in early childhood. The psychologic picture is a complicated one that cannot here be elaborated, but in turn, the obesity in some measure serves as defense against the possibility of exposure to a mature sexual life.

The opposite picture, the extreme of anorexia nervosa, also expresses an unsuccessful struggle of the adolescent with emotional problems too great for him to cope with. Here again one is dealing with extremely anxious young persons so disturbed that their recourse to illness amounts to a suicidal threat. Again a consistent picture of deeply disturbed familial and childhood relationships is encountered. Neurotic disturbance of one or both parents creates a situation in which the child lacks the security provided by normal parental affection and wise training and guidance. Instead, intense hostile and dependent attitudes are fostered. The female patients rather consistently are involved in threatening pregnancy phantasies and defend themselves against the possibilities of growing to maturity, and specifically against the phantasies of pregnancy, through self starvation. Dr. Ruth Moulton[2] among others has clearly exposed the psychodynamics underlying the illnesses of these young persons.

The treatment of the problems described is primarily a psychotherapeutic task. It may be relatively simple or extremely difficult, depending on such factors as degree of regression and the capacity of parents to cooperate. Often neurotic parents unwittingly interfere seriously with the efforts at therapy, and the patients frequently are highly resistive to efforts to help them abandon the destructive patterns. But many adolescents can accept psychotherapy designed to clarify to them the nature of the basic reactions of anxiety and hostility and are able to reorient themselves in a manner approaching that of the healthy adolescent.

CONFLICT WITH AUTHORITY

A constant concern to parents and educators is the conflict with authority that arises with many adolescents. Adolescents do not like to be told what to do. At the same time they are not always in a position to convince their parents that they are capable of self direction. Parents often remain too mistrustful as to the degree of responsibility and self direction which they may entrust to their adolescent children. This theme has many variations.

The parents of a boy aged 13 complained of his lack of responsibility. He was argumentative, would accept nothing readily from his parents. He argued constantly with his younger brother and with his friends. He was impatient unless his friends would do just what he wanted to do. He did rather poorly in his school work, did not concentrate, "fiddled around." He was rather slender and did poorly in athletics. He whined, acted silly when the mother had company, so that she was ashamed of him and sent him from the room; seemed generally unhappy; spent a great deal of time reading; was unpleasant about family outings; did not even like to accept when the father invited him to go to a motion picture with the father and the younger brother; always felt abused and identified with the underdog.

The picture as seen from the boy's point of view is interesting. Though 13, he had never been allowed to come into town by himself and was accompanied to the office by the mother until she was sure he had learned the way. The boy complained that there was too much arguing with the mother and when he got irritated with her the father chimed in on her side. His father offered to take him to motion pictures and insisted even when there was no picture which the boy cared to go to. He finally went because his father would be angry or the father's feelings would be hurt. His mother insisted that he come in to greet her friends when she had visitors, but she watched him all the time to see how he behaved and he knew that she did not want him to stay. When he decided he would like to have a party, the mother first insisted that he have all the children in his room and it took him two days to convince her that would be too many. Then the mother wanted certain children of her own friends invited, but he knew that they would not have a good time because they went to different schools and "the kids do not know them." Finally he got it down to just one girl that mother insisted on, though he knew that the others would not want her and he did not think that she would have a good time.

These details tend to highlight the familiar conflict between parents still too mistrustful of the child's capacity for self guidance and the relatively insecure adolescent who wants to manage on his own. In actuality, the children of this age need and readily accept considerable guidance, but it must be offered in a manner that takes full cognizance of their need to exert their own prerogatives. The disturbed relationship in the case situation described tended to further distinctly unhealthy trends in the character development of the boy. A sullen withdrawal, with exaggeration of resentful, hostile attitudes toward parents and other adults, uncertainty and mistrust about what he himself is capable of doing, the growing conviction that he is always at a disadvantage, tend to become established.

[2] Moulton, R.: A Psychosomatic Study of Anorexia Nervosa, Psychosom. Med. 4: 62, 1942.

The familial conflict may play off in other relationships.

A high school boy of very superior intelligence, who had hitherto given a good account of himself both academically and in his conduct and attitudes in school, was referred for advice because of rapid deterioration in his school work that threatened failure in his senior year, and because of increasing difficulties in his relations with the faculty. His attitude seemed to be that rules were absurd; if there were rules he was an exception and need not conform; they made no sense, etc. It must be remarked that his school was a most liberal one, in which much freedom was given the students. His parents made no complaint about his conduct in the home except that he was most uncommunicative and had to be left strictly alone.

The boy at once took a most superior air with the therapist, began by carefully explaining the absurdities of the rules that got him into difficulty, and questioned the right of the school to impose any restrictions unless he were utterly convinced that they were necessary, etc. He soon shifted his tack, demanded of the therapist whether he had read Wylie's "Generation of Vipers," and expounded a philosophy of life, derived from his particular understanding of this work, that rested on a profound depreciation of the common man and on convictions about the overwhelming significance of an intellectual elite. Factually, this boy's truly superior intellectual capacities do place him at a high level as compared with high school students in general, but the healthy student does not arrive at the orientation expressed by this boy. Further discussions made clear that there was good reason for his cynical attitude. The boy gave an account of a deeply disturbed family life, in which he had much good reason to be anxious and disappointed about his father. Though the father was a professional man who had achieved reasonable success in his field, he was weak and vacillating and betrayed dependent and unrealistic attitudes that deeply disturbed the boy. As his own unfavorable appraisal of his father impressed itself on him, this boy turned against all the adults in his environment and became as critical of and resentful toward his teachers (among whom were a number of men) as he felt toward his father. His overly independent, nonconforming behavior in school followed. His readiness to accept a philosophy of depreciation of most of mankind corresponds with his disillusionments about the authoritarian person in his family. The concept of the intellectual elite who would guide the destinies of mankind reflect a possible solution in which one need not expect much from any one but oneself—and still have life be possible.

ANXIETY STATES

While all the clinical situations referred to involve reactions of mistrust, discomfort and anxiety in adolescents, a word further about anxiety states as such seems in order. Without specific somatic symptoms or disturbances in overt behavior or in the externals of personal relationships, many adolescents exhibit states of anxiety that, at times, seriously threaten their capacity to proceed normally in school work and ordinary routines. When such states of anxiety exist, a careful inspection of the childhood and adolescent experience will usually reveal (*a*) lacks or errors in childhood training or rearing and in child-parent relationships that make it difficult for the child to accept and cope with his situation and (*b*) a recent or current situation that is immediately threatening or overwhelming and that acts as precipitant or augments long-standing discomfort. Examples may be of the following order:

A high school student had always been able to remain on the honor roll, got high grades and had much status on this basis. He was somewhat undersized, but able to participate in sports and athletic activities with some degree of distinction. He drove himself rather mercilessly in this latter activity. He was the only son, in a family in which his anxious mother continued to play a highly overprotective role. With a change in school, the last year in high school, the boy found the work more difficult; he did not do quite as well as he formerly had in a set of examinations, and thereafter became acutely anxious about his school progress. He worried about anticipated examinations to an extent that made it difficult to do any studying at all. About this time, his group of boy friends were paying more attention to social affairs involving the girls, made more dates. He vacillated between going along and feeling that he should spend all his time studying to catch up with his work. In the meantime his mother became greatly concerned about her son's welfare, watched him closely, took him to a number of doctors who found nothing specifically wrong, and this caused more concern. This truly intelligent and capable boy, most dependently attached to an overanxious mother, was able to make a good adjustment as long as it could be on the basis of being the honor student. His general social adjustments were fairly good, though maintained at too great a cost in terms of his overstriving for prestige in sports. His defense against anxiety was successful until a heightened tempo of demand in the school made it difficult for him to maintain his high academic status. With this cornerstone of security shaken, he was ill prepared for the additional demands of blossoming social exposure and the expectation that he cope with the girls, not as his mother's compliant son, but as a more independent young man. This combination of circumstances was sufficient to provoke the state of anxiety that in turn sabotaged his effectiveness in meeting current school and personal situations.

This theme has many variations, and must be understood not only by physicians, but by educators, who must be prepared to recognize and, if possible, offer help to the student so discomfited. Often the break between high school and college is the time at which disturbances of the nature of anxiety reactions are encountered. The educational difficulties which young persons encounter may, to be sure, be primarily of the order of problems of special interests and capacities. Here the task is one of direction and guidance, having in mind the particular fields of learning in which a student may be expected to find the most stimulus and satisfaction. But so often, whatever his special interests and capacities may be, the student may be devoting so much energy to his problems of inner adjustment as to make him relatively ineffective in any field of academic interest. It is this factor of emotional and social maturity or immaturity that is understood in some school settings, given lip service in some and just not comprehended in others.

In academic settings where particular emphasis is placed on acceleration, with the view to telescoping the years of general education, the too exclusive emphasis on the "academic" aspect of the educational experience constitutes a danger to a certain number of the young persons involved. Assuming the intellectual equipment requisite for grasp of the material presented, the intellectual experience may be integrated with socially and emotionally maturing experiences that together constitute a healthy and successful educational experience. By successful, I would mean an increased capacity to understand and cope with his world of experience.

But it is quite possible, with many young persons, that the intellectual experience proceeds in a somewhat isolated fashion. I have already indicated the capacity of adolescents to intellectualize and to use an intellectualizing defense in their inability to cope with the emotionally disturbing aspects of their life relationships. For this reason, adequate progress in intellectual achievement is not in itself a sufficient criterion for success of the educational experience. There needs to be the assurance that in the personally meaningful relationships between student and faculty and student and student the real need of the adolescent is met. The details of this consideration are many and cannot here be discussed; my point is that this important element in the educational provisions for the adolescent is not sufficiently understood. So often the failure of the experience is appreciated only if the student actually fails to make good in his school subjects, because certainly the discomfort of a most intelligent student may reflect itself in academic failure. Failures in the fields of emotional and social orientation are frequently overlooked and more often not understood. They become apparent when the student later runs into actual difficulties in adapting to vocation—to marriage and parenthood.

I do not propose to discuss specifically the question of sexual education of the adolescent. There is no special sexual education of the adolescent, because his sexual education has been in process since earliest childhood. Sexual education is not merely a matter of exposing a child to "the facts of life" at a given age considered appropriate, important indeed as that aspect of education may be. The sexual orientation of the adult is compounded of a synthesis and integration of gradually changing and evolving attitudes and values based on the healthy experience of family life. The experience of being loved and cared for in infancy, and having a live concept of what an adequate mother and father are like, the experience of learning the give and take of family life with brothers and sisters, the experience of being accepted as an adequate boy or girl by the parents, the discovery of the capacity to be successful in meeting ordinary life situations and in adapting oneself to new situations; all of these add up to sexual education. The deficiencies of this earlier life experience tend to be highlighted during adolescence, because the growing boy or girl finds himself more imminently faced with the actual problems of sexual life. For the emotionally healthy boy and girl, the evolving social opportunities of high school and college years can gradually be utilized in achieving the understandings that lead to ultimate courtship and marriage. It is during this period, however, that much preventive work can be done in helping the insecure or emotionally disturbed adolescent. The problems centering about sexual strivings and sexual behavior should be dealt with openly and realistically.

THE GENERAL PROBLEM OF PSYCHOTHERAPY

This leads to a final commentary on the general problem of psychotherapy in adolescence. Any relationship with an adolescent has the possibility of being of therapeutic value. Most young persons are highly sensitive to the personalities, the attitudes of the adults with whom they have contact. Teachers and doctors particularly are in a position to affect the young person profoundly at times. Among educators, the intent is educational, not therapeutic; yet there are situations in which a distinction can hardly be made. The mere acceptance of an adolescent on a fairly adult level by an instructor whom he respects may have a rather positive effect on an insecure adolescent. The willingness of a doctor to review disturbing family or personal situations, free of the complication of familial attitudes toward the adolescent, can similarly be utilized. If the adult is capable of really understanding an unfolding problem exposed to him by an adolescent, the chances are great that the young person can share that understanding, unless he is neurotically seriously disturbed.

Unfortunately, with more serious disturbances, there at times must be a considerable uncovering of uncomfortable and disturbing earlier experience or present attitudes. For this reason, psychotherapy with adolescents offers certain difficulties and dangers. Adolescents, disturbed in their family relationships, are likely to act out their dissatisfaction with the family more freely, for a period during treatment, than ever. Unless parents are fully prepared, they tend to become disturbed by such possibilities and are unable at times to cooperate in treatment. With all patients in psychotherapy, it is important that the physician be quite cognizant of the patient's capacity to tolerate, assimilate and make constructive use of whatever he may be confronted with in the course of therapy. For adolescents, this is particularly important. But if the physician fully understands this factor, and his own relationship to the adolescent and problem, with all except the most disturbed adolescent he finds the ready possibility of helping the patient to a more effective and realistic manner of dealing with his life situation.

PERITONEAL IRRIGATION

Successful Use in the Treatment of a Case of Renal Failure Due to Mercurial Nephrosis

and
J. W. HINTON, M.D.
New York

Use of the peritoneum as a dialyzing membrane in the treatment of uremia following acute renal failure has been under careful investigation recently by Fine and his associates.[1] Their goal has been to provide "a temporary substitute for the normal excretory function of the kidney," and so to prevent deterioration and death from uremia during the period necessary for the repair of acute renal damage. They reported an instance of cure in a case of uremia due to sulfathiazole toxicity.[2] Subsequently, Goodyear and Beard [3] were successful in treating a case of acute renal failure due to a transfusion reaction in a patient with a solitary kidney. Several other successful results are known to us, but have not yet appeared in the literature. To the best of our knowledge this is the first successful application of the method of peritoneal irrigation to a case of renal failure due to mercurial nephrosis.

From the Department of Surgery, Surgical Research Laboratory, New York Post-Graduate Medical School and Hospital.

TECHNIC

The technic employed was that of Fine, Frank and Seligman,[1b] with several slight modifications. Monobasic sodium phosphate was omitted from the irrigation fluid because of the hyperphosphatemia which usually accompanies uremia.[4]

To 19 liters of freshly distilled water in a "pyrex" carboy the following anhydrous substances were added: sodium chloride, 160 Gm.; potassium chloride, 4 Gm.; calcium chloride, 2 Gm.; magnesium chloride, 2 Gm., and dextrose, 30 Gm. The carboy was then autoclaved for ninety minutes and allowed to cool for five or six hours. Simultaneously, in a 2 liter flask, 20 Gm. of sodium bicarbonate was dissolved in 1 liter of distilled water and autoclaved for forty minutes. When both solutions were thoroughly cool, the sodium bicarbonate was added to the carboy to make 20 liters of modified Tyrode's solution. Just prior to use, 10 mg. of the sodium salt of heparin, 1,000,000 units of penicillin and 1 Gm. of streptomycin were added. The remainder of the apparatus was that described by Fine and associates.[1b] A rubber catheter was inserted through a short paracostal incision high in the right flank to function as the inlet tube, while a stainless steel sump drain was placed into the cul de sac through a McBurney incision in the left lower quadrant for use as the outflow tube. It was connected to a suction motor, regulated by a water trap to supply suction at a negative pressure of about 12 inches (30.5 cc.) of water.

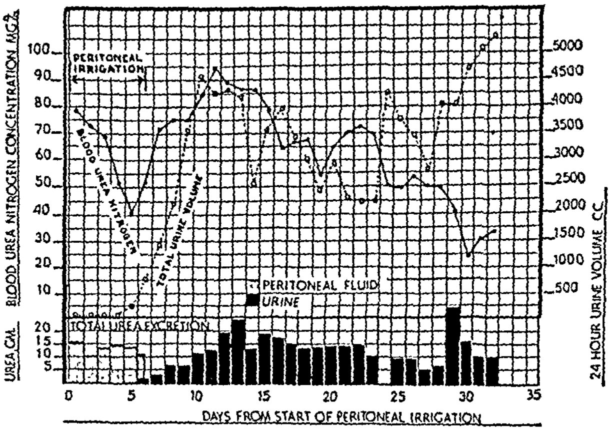
[4] Seligman, A. M.: Personal communication to the authors.

Insertion of both tubes was accomplished in the operating room with the patient under local anesthesia.

The rate of flow was kept at about 2,500 cc. per hour for one day, after which a kink in the inflow catheter and clogging of the Mandler filter slowed down the flow to about 1,500 cc. per hour. The patient was comfortable in a slight Fowler's position and experienced no pain throughout six days of irrigation. Collateral chemotherapy consisted of penicillin 50,000 units every three hours intramuscularly and streptomycin 333 mg. every four hours by mouth for twelve days.

REPORT OF A CASE

The patient was a white bipara aged 32, transferred to the service of one of us (J. W. H.) from her community hospital with a history of having swallowed at least 4 tablets (2 Gm.) of bichloride of mercury about seventy-eight hours previously, in an attempted suicide. It was stated that the patient had experienced a small bloody emesis about fifteen to twenty minutes thereafter. Gastric lavage was carried out about one hour after the mercurial compound was taken. Peripheral vascular collapse had been treated with prompt transfusions of plasma and blood. BAL (2,3 dimercaptopropanol) was rushed to the patient from a neighboring city, but over four and one-half hours elapsed before the first dose could be administered. She received a total of 1,900 mg. of this drug intramuscularly over a sixty-six hour period. During this time the patient had a severe and persistent bloody diarrhea. Parenteral fluid therapy was given daily but the patient was stated to have been completely anuric from the time the poison was taken until she came under our observation three days later.



Showing blood urea nitrogen, total volume of urine and total excretion of urea.

On admission to the New York Post-Graduate Hospital the patient was alert and oriented but uncooperative and depressed, with evidences of a psychotic mental disorder. Heart and lungs were clear. The abdomen was soft and not tender. The temperature was 99.4 F., pulse rate 128, respiration rate 24 and blood pressure 132 systolic and 90 diastolic. The red blood cell count was 4,120,000; hemoglobin 13.0 Gm.; white cell count 16,150, of which 84 per cent were polymorphonuclear cells. The nonprotein nitrogen was 106 mg. per hundred cubic centimeters, while the blood urea nitrogen was 75 mg. per hundred cubic centimeters.

Shortly after admission and about eighty hours after the ingestion of poison, peritoneal irrigation was begun. During the first two days of irrigation the patient passed about 30 cc. of grossly bloody urine each day. This was accompanied by a severe bloody diarrhea. On the first day a 500 cc. blood transfusion and 1,000 cc. of 10 per cent dextrose in water with large amounts of vitamins B and C were administered. A moderately severe ulcerative stomatitis developed, which did not prevent the patient from eating. The stomatitis slowly responded to local treatment. The patient was kept on a full soft diet with carbohydrate supplements in the form of sweet drinks and hard sugar candy, which she took fairly well throughout the period of irrigation.

In an attempt to correct acidosis, on the second day 1,000 cc. of one-sixth molar sodium lactate was given intravenously with no improvement in the carbon dioxide-combining power (table 2). Therefore, on the third day, 22.5 Gm. of sodium bicarbonate in 1,000 cc. of 10 per cent dextrose in water was administered intravenously, very slowly. Subsequently, there was definite improvement of the acidosis. On the second hospital day a significant amount of fluid began to leak around the outflow tube. This persisted to some extent throughout the remainder of the treatment.

Four days after the onset of irrigation, pronounced pitting edema was noted in the dependent portions of the body. Five hundred cubic centimeters of plasma was given in an attempt to ameliorate the severe hypoproteinemia. Digitalization was accomplished with 1.2 mg. of digitoxin divided into two oral doses. Despite the presence of edema, 10 Gm. of sodium bicarbonate were administered by mouth to control acidosis. At the same time the patient began menstruating. Since it became difficult accurately to ascertain the urinary output, an indwelling Foley catheter was inserted at the start of the fifth day. At this time the urine output increased to 217 cc., although the specific gravity and urea concentration remained low. In an attempt to remove some of the edema fluid via the peritoneal route, the irrigating fluid was modified slightly and 1 per cent gelatin was added, while simultaneously 30 Gm. of salt-poor human serum albumin was given intravenously on the fifth day with only slight success. The lungs remained essentially clear to auscultation at all times.

At the end of five and one-half of irrigation (eight and one-half days after ingestion of poison), the output of urine had increased to 725 cc. and the blood urea nitrogen had been reduced to 51.5 mg. per hundred cubic centimeters. Peritoneal irrigation was then discontinued. The red blood cell count at this time had declined to 3,400,000; the hemoglobin to 10.3 Gm.; the white cell count was 15,050. The patient's temperature had never exceeded 100.6 F. Although there was moderate abdominal distention on the fifth and sixth days, it never became a serious problem, nor was there ever any clinical evidence of peritonitis. The patient's stools had been brown in color since the third day but were extremely soft; no further gross blood was noted, although tests for occult blood were positive for several days. Cultures of the outflow fluid were made each day, and remained sterile until the last day of irrigation, when Escherichia coli and nonhemolytic streptococci were found.

After cessation of peritoneal dialysis, the blood urea level rose for five days despite the large volumes of urine which were excreted (the figure). Clinically, however, there was improvement, and the patient was out of bed on the eighth day after admission. Because the kidneys were as yet apparently unable efficiently to conserve base, the patient's carbon dioxide-combining power fell to 36.2 volumes per cent on the eighth day. This state of acidosis successfully was counteracted by administration of 1,000 cc. of one-sixth molar sodium lactate intravenously. Thereafter, acidosis never became a serious problem, although the urine continued to be alkaline in reaction throughout the patient's hospitalization. The specific gravity varied from 1.006 to 1.010 and there was a faint trace of albumin during this entire period. No glycosuria, hematuria or pyuria was noted during the period of recovery.

Digitoxin was discontinued on the ninth hospital day. From the ninth through the thirteenth day the patient's urinary output far exceeded the total fluid intake and her edema entirely disappeared. Blood transfusions of 500 cc. each were given on the twelfth and the thirteenth day because of a decline in the red blood cell count to 2,600,000.

In view of the steadily rising blood urea nitrogen level, an attempt was made to reduce the quantity of nitrogenous excretory end products by reducing the dietary protein to 40 to 50 Gm. daily after the twelfth day. Three hundred grams of carbohydrate was given daily to achieve as much of a "protein-sparing" effect as possible. By the fifteenth day after the start of peritoneal dialysis, the concentration of urea nitrogen in the blood began a slow but progressive decline. On the thirty-third hospital day, the patient was transferred to a mental hospital because of the urgent need of intensive psychotherapy. The renal function was still poor with the urea clearance averaging only 10 to 15 per cent. of normal

COMMENT

Although this patient on admission was not moribund and did not exhibit the signs of severe uremic intoxication, it was evident that the prognosis was poor, despite the use of BAL. If BAL is to achieve optimal results in preventing renal and gastrointestinal protoplasmic destruction, it must be administered within three and one-half hours of the ingestion of bichloride of mercury.[5] In this case BAL was not available for four and one-half hours and failed to prevent profound renal damage.

Anuria of twenty-four hours' duration or more was noted by Hull and Monte [6] in 40 cases of mercurial poisoning. This occurrence carried with it a mortality of 92.5 per cent. If the anuria persisted for three days, the mortality in their series was 100 per cent. In this case anuria was present for over three days, and severe oliguria for four days more. A blood creatinine level of 5 mg. per hundred cubic centimeters was likewise considered of poor prognostic import by these authors. This patient's creatinine rose to a height of 9.5 mg. per hundred cubic centimeters two days after peritoneal dialysis was discontinued, probably a reflection of widespread tissue protein destruction by the mercurial, as well as failure of the damaged tubules to excrete creatinine.

On the other hand, tubular regeneration has been noted as early as three days after the onset of mercurial nephrosis,[7] provided that the patient does not succumb in the meantime to the effects of uremia. For this reason, and also because the patient was still in fairly good physical condition, it was considered that this was an ideal case for peritoneal irrigation. The patient was never comatose or delirious and was able to take a full soft diet by mouth. It was not necessary to restrict the protein intake during irrigation, because of the efficiency of the peritoneal dialyzer in removing the nitrogenous end products of protein metabolism, although after cessation of dialysis, protein restriction was considered necessary so far as the blood urea nitrogen concentration was rising.

The method employed succeeded in removing more than 75 Gm. of urea over the five and one-half day period of operation. The quantity of urea actually removed was probably much greater than this but could not be measured because of the considerable leakage of fluid around the outflow tube. Based on the material collected and analyzed, the daily urea excretion and urea clearances are given in table 1.

We are able to confirm the findings of Fine and his group [8] that peritoneal irrigation can serve as a satisfactory temporary extrarenal pathway of elimination of urea and the other excretory products whose accumulation in the body fluids leads to uremia and death. It is considered that the urea clearances achieved by the peritoneal dialysis in this case could have been increased by running in the fluid at a more rapid rate of flow. It should be noted that promptly after discontinuing irrigation the blood urea level rose from 51.5 to 72 mg. per hundred cubic centimeters and eventually to 94 mg. despite urine output volumes as high as 4,500 cc. per day. One factor contributing to this elevation of blood urea nitrogen was the presence of considerable edema fluid which probably served as a temporary "reservoir" of urea, and similar diffusible excretory products with which the poorly functioning renal tubules were forced to contend. Probably the most important factor in this case, of course, was the persistence of tubular damage with fixed urinary specific gravity and low urine urea concentration.

The most serious difficulty encountered in the management of this case was the treatment of acidosis in the presence of hypoproteinemia and pronounced dependent edema. Despite the danger of pulmonary edema, the patient was treated with intravenous or oral sodium bicarbonate whenever a low carbon dioxide-combining power seemed to warrant such treatment. It was noted that intravenous sodium lactate therapy was not successful in combating acidosis while the peritoneum was being irrigated, although it served its purpose well after irrigation was discontinued. The reason probably was that the lactate diffused out into the peritoneal fluid before the body had an opportunity to metabolize it. Sodium bicarbonate was effective during the irrigation because the irrigating fluid contained the bicarbonate ion, thus preventing great losses by this route. It is felt that further investigational work needs to be carried out before control of both edema and acidosis may be achieved by altering the irrigating fluid to fit each case individually. However, as presently constituted, the irrigation fluid was effective in keeping the blood chloride and calcium concentrations at normal levels in this case.

Finally, it is important to emphasize that this method is a formidable one and should be used only in cases in which a fatal result by conservative treatment seems beyond reasonable doubt. The great danger, of course, is the development of peritonitis.[9] E. coli were cultured from the outflow fluid in 3 of the 4 cases reported by Fine, Frank and Seligman,[1b] although clinical peritonitis did not occur. In this patient, E. coli and nonhemolytic streptococci were cultured on the last day of irrigation. The frequent occurrence of E. coli would indicate that the origin of the peritoneal contamination is probably due to migration of organisms through the wall of the intestinal tract. Severe distention and ileus may enhance such migration. We have attempted to counteract this source of peritoneal contamination by giving streptomycin orally, but cannot determine on the basis of this experience alone whether the procedure was of value. It has been pointed out that prophylactic use of streptomycin in the irrigating fluid leads to the rapid development of resistance to the drug on the part of the organisms.[9a] The problem of peritonitis constitutes the most serious limiting factor in the use of peritoneal dialysis as a clinical therapeutic method.

CONCLUSION

Peritoneal irrigation has been successfully applied to the prevention of uremia in a patient with anuria due to mercurial nephrosis.

NOTE.—Seven months postoperatively the patient still had intermittent mild azotemia, with 20 to 30 mg. of urea nitrogen and 2 to 3.5 mg. of creatinine. Ten months postoperatively the chemical content of the blood was normal. She had returned to her home from a psychiatric hospital following treatment, and she was carrying on her household duties with no apparent physical or mental difficulty.

ARTIFICIAL KIDNEY

GORDON MURRAY, M.D.
assisted by
EDMUND DELORME, M.D.
and
NEWELL THOMAS
Toronto, Canada

It is impressed on every physician occasionally and on some ill fated patients at short intervals that renal function is a vital one. The sudden onset of acute anuria following blood transfusion, the acute toxemias of pregnancy and otherwise, following certain poisonings or the administration of sulfonamide drugs, etc., sets off an alert in the attending physician. With reasonable luck, many of these patients will recover function within a few hours or days, when the "stand easy" signal arrives, with great relief to the physician. However, if such fortuitous circumstances do not establish themselves, after the fifth or sixth day of anuria the physician is faced with an ominous set of circumstances over which he has little control. There are the average and orthodox methods of treatment, but, by and large, these have relatively little effect in changing the course of events which are indicated by the acute anuria. At this stage the physician in attendance invariably questions himself whether there is not some way of escape from the fatality which must ensue if the anuria persists. Time and again physicians have asked themselves, if some artificial kidney could be applied at this stage, what an important change it might make in the course of the individual patient.[1]

It was with great satisfaction, therefore, after many years' work on attempting to replace renal function by artificial means, that we were able to produce a machine (fig. 1) which will reproduce the function of the kidney, will reduce the nonprotein nitrogen substances in the blood stream and tissue fluids as well as the fixed cells themselves and remove many, if not all, the toxic substances that cause the fatal result in the cases of anuria. Obviously this machine can function only as a temporary measure. It was assumed, however, if the patient could be prevented from dying of toxemia, that eventually the kidney, in the cases of acute disease, might be given time to repair itself sufficiently that it might begin to take over, and finally restore natural renal function. Experimentally with uremic animals we were able to provide this effect, and in patients as well the toxemias have been reduced so that unquestionably several patients have survived following treatment with this machine who otherwise were doomed to nonsurvival from a state of acute uremia from anuria.

My original efforts in this direction were in an attempt to transplant kidneys from one animal to another in the same species, then from one species to another. It was demonstrated about fifteen years ago[2] that the renal function could be taken over by a transplanted kidney and that an animal with his own kidneys removed could live for a time on the function of the transplanted kidney. At a later stage different methods of attempting to dialyze the blood of the uremic animal were made, and it was finally with satisfaction that we were able to use a cellulose membrane with the proper apertures so that the crystaloids, the nonprotein nitrogen substances and toxic substances would escape whereas the large molecules, such as proteins, hormones such as pituitrin, epinephrine, insulin and heparin, would not escape (table 1). The problems in this work came under the following headings:

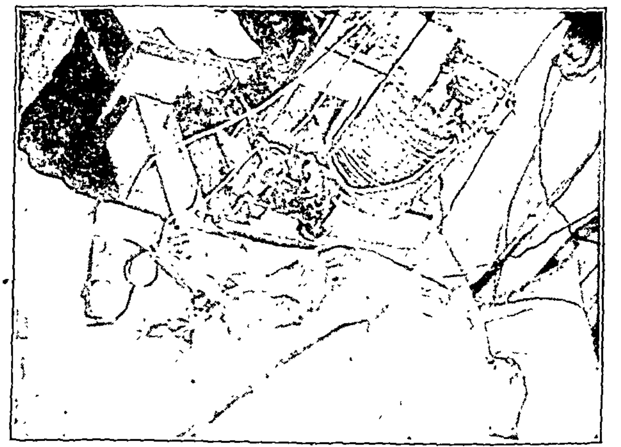

Fig. 1.—Photograph of artificial kidney in use on a patient.

1. A method of removing the blood for dialysis, then returning it to the subject presented the first problem. Many experiments were done and many methods used; we began by using arterial blood with arterial blood pressure as the circulating pressure, then returning it through the venous system. Finally, however, the present method, which is satisfactory and has worked rather well in clinical patients, has been to remove the blood from the inferior vena cava and return it through the opposite iliac vein. By this method a sufficient flow of blood can be obtained without obstruction and there is no ill effect either on the experimental animal or on the patient.

2. The method causing this blood to circulate was experimented with. The first efforts were by removal of volumes of blood from the subject, dialyzing it and then returning it as a separate transfusion; this worked satisfactorily but it was laborious and was too slow in its operation. For that reason a method of continuous circulation of the blood through a tube seemed to be ideal and when ultimately developed worked satisfactorily. At the present time an efficient pump for

---

Prof. H. B. Van Wyke, Prof. J. McClelland and Dr. W. G. Cosbie provided the patients whose records of treatment are reported. Laboratory space and some chemicals were furnished by Prof. Andrew Hunter, of the Department of Pathological Chemistry. The Department of Experimental Research provided experimental animals and space in which to work.

causing this circulation, removing the blood from the vena cava, circulating it through the apparatus and then returning it, is a satisfactory method. It will continue to function for hours on end without difficulty and, provided the blood in the apparatus as well as that in the subject being treated is adequately heparinized, there are no difficulties whatever.

3. The next problem was one of dialyzing the membrane to produce the desired effect and not to produce any untoward effect. It was demonstrated early in the work that if such a membrane was surrounded only by tap water the experimental animal quickly showed ill effects from the procedure. There were pronounced ill effects on respiration and blood pressure, and within ten to fifteen minutes the animal succumbed from loss, or addition to, his circulation of important substances. However, it was found that provision of sodium chloride solution as the bath surrounding the dialyzing membrane caused some improvement, and finally by the addition of various substances, including the list in table 2, the dialysis could be carried on for hours or days without causing any ill effect in the animal or on the patient clinically. It was found that the crystaloids, sugar and water escaped rapidly through the membrane. By adequate buffering of these substances in the surrounding bath or dialysate, it was possible to prevent any ill effect.

Table 1.—*Showing Changes in Nonprotein Nitrogen in Blood of Dog During Two Hours' Perfusion by Artificial Kidney*

	Blood Nonprotein Nitrogen Mg./100 Cc.	Plasma Content, Mg./100 Cc.
Blood, after 20 minutes' perfusion, going into apparatus	39.5	110
15 Gm. urea in saline solution added; blood, after 80 minutes, going into apparatus	130.2	115
Blood, after 80 minutes, coming out of apparatus	122.6	109
Blood, after 2 hours, going into apparatus	98.0	112
Blood, after 2 hours, coming out of apparatus	82.4	112

Table 2.—*Formula to Make 18 Liters of Perfusion Fluid*

Ingredient	Amount, Gm.
Sodium chloride	114
Calcium chloride	1.8
Magnesium chloride	1.8
Sodium phosphate	0.9
Dextrose	27.0
Potassium chloride	3.6
Sodium carbonate	18.0

The diagram (fig. 2) shows the simple principles of this machine as it works in action. It was discovered by doing estimations of nonprotein nitrogen on the dialysate that the nonprotein nitrogen substances escaped fairly rapidly though the dialyzing membrane and their accumulation in the dialysate slowed up the rate of dialysis. By changing the dialysate at short intervals the rate of dialysis is kept at a relatively high speed. It was demonstrated that with a length of about 35 feet (10.7 meters) of this tubing about 0.75 Gm. of nonprotein nitrogen substances will pass through this membrane each hour. The result of this on the uremic animal or on the clinical patient was striking. From a state of uremia, the subject returned to a state of more normal health.

With this apparatus it was possible to fractionate the blood of a toxic animal or patient, and it gave an opportunity for study of the substances which were causing the toxemia. We have demonstrated experimentally that, if an animal was given an injection intravenously of urea which raised the level at least five times above that of the level of an animal dying of uremia, it caused little ill effects. With the machine working, the urea could be removed again without difficulty (table 1).

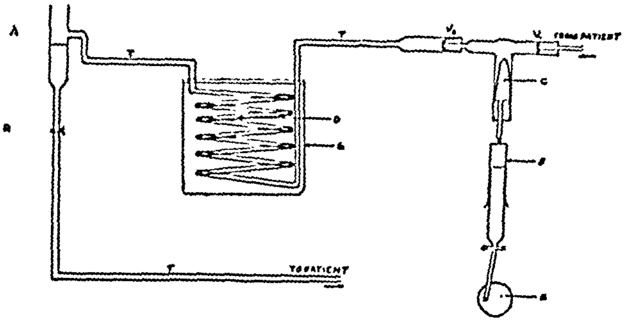

Fig. 2.—Schematic diagram of artificial kidney.

This suggests that the substance causing the disease and illness of the patient in uremia is not the nonprotein nitrogen substances but is comprised of other substances which are removed by this membrane.

Experimentally we have demonstrated that when an animal is having a deficiency of oxygen, produced in various ways, a fairly large quantity of oxygen can be supplied by this machine. Moreover, the blood stream of the animal could be supplied with almost any desired quantity of sugar or other crystaloids by addition of these substances to the dialysate, but this requires a great deal more investigation. There was some evidence to suggest that by use of this apparatus various types of medication and treatment might be given for various conditions such as traumatic shock or following severe burns.

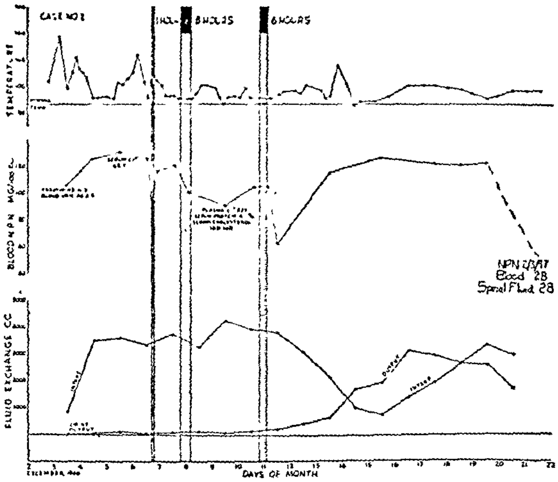

Fig. 3.—Showing the effects of dialysis in a uremic patient.

While we have treated several clinical patients with this apparatus, there are 3 cases in particular which are reported herewith to illustrate the function and effect of this apparatus.

REPORT OF CASES

Case 1.—The patient was 26 years of age. After an attempt at inducing abortion, acute anuria developed. The patient was seen on the ninth day, after treatment by the physicans, the gynecologists and the genitourinary surgeons had been discontinued because it was thought that the patient had no hope of surviving. Professor Van Wyck enabled us to see this patient. At that time she had pronounced uremia. She was semicomitose and having minor uremic convulsions. She was secreting from 4 to 30 cc. of urine only, in twenty-four hours, and chemical analysis of the blood (fig. 3) showed uremia.

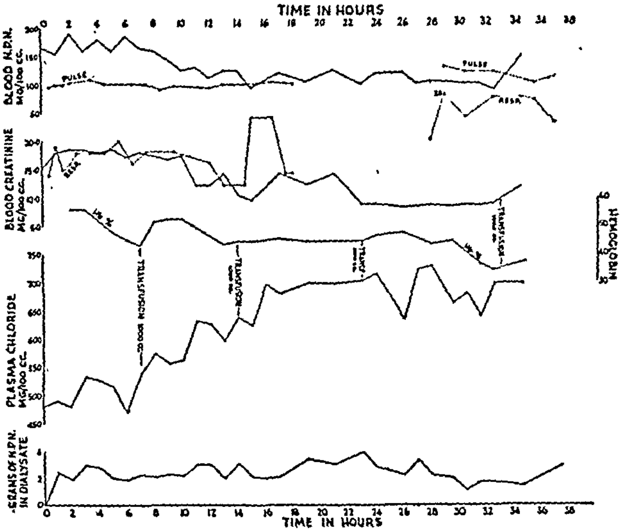

Fig. 4.—Showing chemical changes in the blood of patient during dialysis over a period of thirty-six hours, with removal of 72 Gm. of nonprotein nitrogen

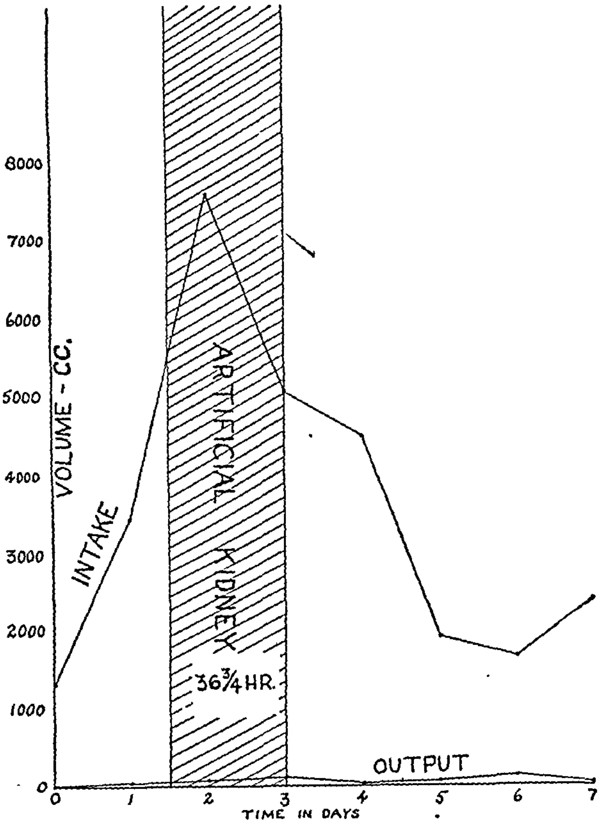

Fig. 5.—Showing fluid exchange of patient previous to, during and following treatment with the artificial kidney (case 2).

Even though the situation seemed hopeless, it was decided to attempt dialysis with this artificial kidney. Cannulas were placed through the iliac vein on one side reaching into the inferior vena cava, from which the blood was removed. It was circulated through the machine and passed into the iliac vein on the opposite side. The patient was heparinized and the blood entering the machine was heavily heparinized. The first run was carried on for one hour, during which 330 mg. of nonprotein nitrogen substances was removed, on estimations done on the dialysate. At this time the patient had a chill and the operation was discontinued. The patient was considerably improved after this. However, forty-eight hours later she had relapsed again and was in a comatose condition. Another dialysis, started at this time, was carried on for eight hours. During this time 6.6 Gm. of nonprotein nitrogen substances was removed, and as a result of this the patient's condition was changed in an amazing fashion. She had become rational, had normal responses and would drink some fluids; everything seemed to be improved. However, there was still no secretion of urine beyond the few cubic centimeters each twenty-four hours. Following the next forty-eight hours the patient was again back in the condition of extreme uremia, and another run of seven hours was undertaken with the artificial kidney. Again the patient's general condition was greatly improved. She was again rational, and things were well on the mend. The day following discontinuation of this run, the patient began to secrete urine; on the day following that, she secreted 4,000 cc., and from then on she made a continuous and rapid recovery. Nonprotein nitrogen in the blood was followed, as well as in the cerebrospinal fluid and in the ascitic fluid in the peritoneal cavity throughout the investigation. It was demonstrated that nonprotein nitrogen in the blood, the spinal fluid and the ascitic fluid diminished rapidly; finally the ascitic fluid disappeared and no further estimations were possible here. Within about one month of the time that the patient was in acute uremia, she was in perfect health and was able to return to work at a clerical job. The last renal function to regain its normal level was that of concentration of urine. At the end of a month she could concentrate on a water two hour test only up to a specific gravity of 1.016. However, at the end of two months the concentration was up to 1.022 and as time progressed beyond this the concentration reached a higher level still. At the present time no abnormality is noted in the urine, the blood pressure or the patient generally.

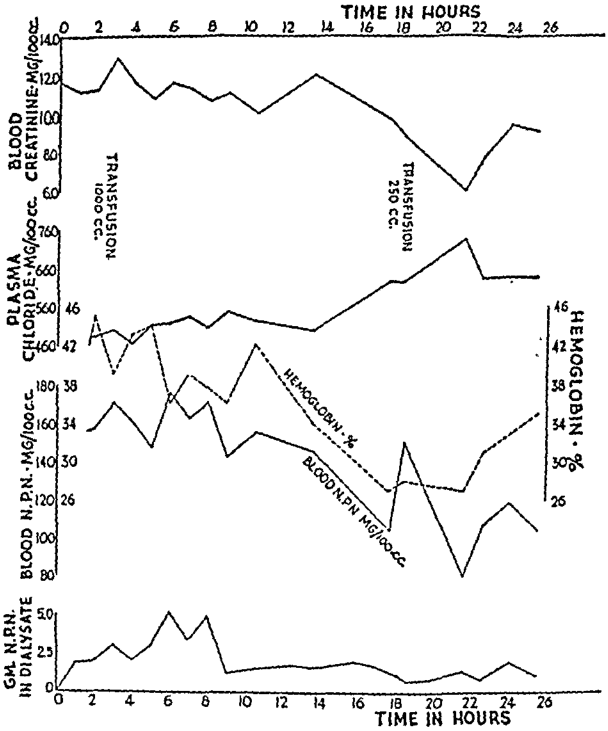

Fig. 6.—Showing chemical changes in the blood during treatment with the artificial kidney (case 3). Total amount of nonprotein nitrogen removed in twenty-five and one-half hours was 49.4 Gm.

Case 2.—Opportunity to see Mrs. C., age 37, was provided by Dr. J. McClelland. This patient had bilateral renal calculi, of which the left had been removed about one year previously. Eight weeks previously she gave birth to a normal child and had no renal complications during or following pregnancy. Fairly suddenly she began to have oliguria, and it is uncertain whether a recent infection of the upper respiratory tract might have been a cause for this.

On admission to the hospital the patient was in poor condition. She had a period of about twelve hours when there was no blood pressure to be demonstrated, no pulse and a severe heart block with a rate of 18 per minute. After suitable medication, the blood pressure rose to 150 systolic and 86 diastolic, but the patient did not regain consciousness, and urinary secretion was only a few cubic centimeters.

After much hesitation because of the poor condition of the patient and the uncertainty regarding the state of the chronic lesion of the kidneys, a decision was made to attempt a dialysis on the artificial kidney.

A successful run, lasting thirty-six hours continuously, was carried out. Fifty-two feet (15.8 meters) of tubing was used. During this time 72 Gm. of nonprotein nitrogen was removed and the charts show the effect on the chemical composition of the blood. In spite of this, the patient did not regain consciousness. It was thought that perhaps the prolonged period (twelve hours) of absence of blood pressure might have caused permanent injury to cerebral cortex. In spite of this, the patient lived seven days; the output of urine during that time is shown in figure 5.

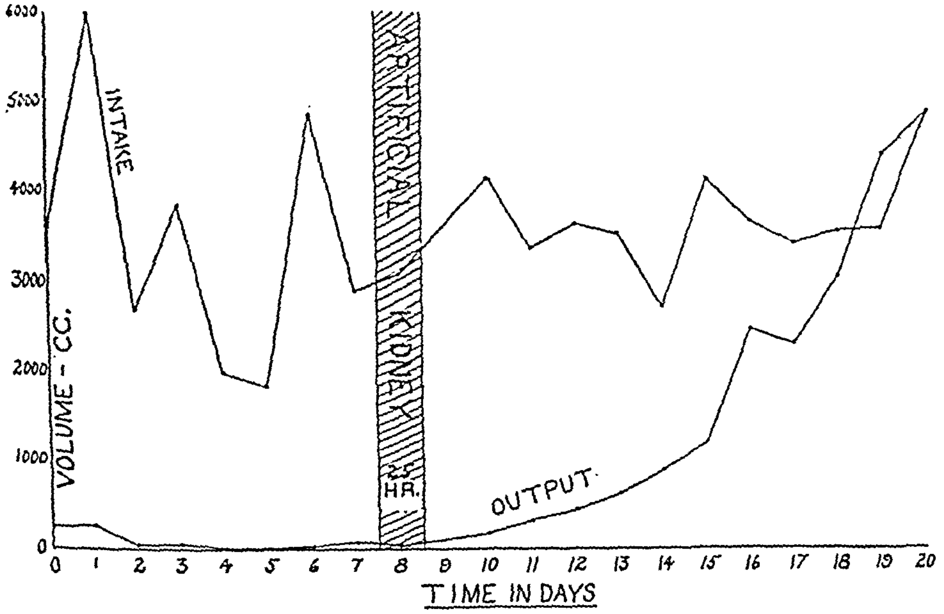

Fig. 7.—Showing fluid balance previous to, during and following treatment with the artificial kidney. The shaded area represents the time of dialysis.

Case 3.—Opportunity to see Mrs. McL., aged 40, was provided by Dr. J. Cosbie.

After caesarean section when a blood transfusion was given, the patient showed oliguria, the urine contained hemoglobin and hematin. She passed only 3 to 5 cc. of urine daily for eight days, at which time the blood nonprotein nitrogen was 0.179 mg. and the patient was showing signs of uremia.

She was then treated for twenty-six hours in the artificial kidney. Fifty-four feet (16.4 meters) of tubing (fig. 6) was used, and 49.4 Gm. of nonprotein nitrogen was removed from the blood. The following day the urinary secretion increased to 210 cc.; the daily increase, up to 5,730 cc. on the twelfth day, is indicated on the chart. The patient gradually improved clinically and has made an excellent recovery. Renal function has returned to normal and the patient is in normal health.

CONCLUSIONS

A method of dialyzing a patient's blood for removing of nonprotein nitrogen as well as toxic substances has been produced which functions satisfactorily and can be used safely.

Clinical Notes, Suggestions and New Instruments

STREPTOMYCIN THERAPY

Effects on Fetus

ERNEST H. WATSON, M.D.
and
ROBERT M. STOW, M.D.
Ann Arbor, Mich.

Two patients, both in the second trimester of pregnancy, received 2 Gm. of streptomycin (0.4 Gm. five times per day) for ninety-five and ninety days, respectively. The blood serum levels ranged between 12 and 25 mg. per cubic centimeter. The first (V. B.) had had a nephrectomy on the right side four years previously, for far advanced caseous renal tuberculosis, and on admission showed evidence of progressive tuberculous involvement of the left kidney and bladder. The second (J. S.) had had primary pleural effusion followed just prior to admission by rapidly progressive far advanced hematogenous pulmonary tuberculosis. In each case streptomycin was felt to offer the only hope for recovery. Because the pregnancies were in the second trimester, it was felt safer to allow them to continue rather than to resort to interruption.

At the time streptomycin therapy was started, V. B. was five and a half months pregnant and J. S. four months pregnant. Both showed improvement during and following streptomycin therapy, though vestibular function was completely lost in each patient. In each case examination of the placenta revealed no gross or microscopic abnormalities.

The patient V. B. was delivered of a female infant by cesarean section at what was calculated to be approximately eight and a half months of pregnancy. The infant breathed and cried at once. The birth weight was 5 pounds 6 ounces (about 2,438 Gm.). The occipitofrontal circumference of the head was 12¼ inches (31.02 cm.) and the circumference of the chest was 11¾ inches (28.13 cm.). This infant was given unusually close observation, but nothing abnormal in its neonatal behavior was noted. She was on demand bottle feeding after 48 hours of age and by 3 weeks of age had reached a weight of 6 pounds (about 2,722 Gm.)—a gain of 10 ounces (about 284 Gm.) over birth weight. Reactions to Kahn and tuberculin tests were negative at 10 days of age, and the reaction to the tuberculin test repeated at 6 months of age was negative. Roentgenologic observations of the chest at 6 months were normal. It was evident from early infancy that the child could hear. There was no nystagmus or other neurologic abnormality to indicate vestibular involvement. This child was 9 months of age at the time of writing. She was able to sit up, play with objects and in general behaved in a normal fashion. She was regarded by several pediatricians and by other attendants as a normal infant.

The patient J. S. delivered a 6 pound 9 ounce (about 2,523 Gm.) boy spontaneously after medical induction at approximately the ninth month of gestation. The infant measured 19 inches (47 cm.) in length; the occipitofrontal circumference of the head was 13¼ inches (33 cm.) and the circumference of the chest was 13 inches (32 cm.). General examination revealed no abnormalities, and it was determined rather early that the infant could hear. No abnormalities were observed in a roentgenogram of the chest. Kahn and routine laboratory tests elicited negative reactions. Considerable regurgitation was encountered for the first two weeks of life, leading to a consideration of several possible diagnoses, but the infant gradually regurgitated less, and by the third week of life normal gain in weight was observed. This boy was followed closely for nearly a year and at the time of writing was regarded as entirely normal. At 10 months he was 28¼ inches (71.76 cm.) in length, weighed 20 pounds (about 9,072 Gm.) and had circumferences of the head and chest of 18 inches (45.72 cm.) each. These are normal measurements. He sat up well, played with objects with dexterity and normal neuromuscular control.

CONCLUSIONS

We realize the danger of drawing conclusions from 2 cases, but thought it would be of interest to report that streptomycin administration during the second or third trimesters of pregnancy did not appreciably harm the infant in 2 instances. We would be hesitant to advise administration of streptomycin during the first trimester because of the generally accepted sensitivity of the fetal structures in the anlage stage during that period. We would welcome further information on the condition of infants born to mothers receiving streptomycin during pregnancy.

Council on Physical Medicine

REPORT OF THE COUNCIL

The Council on Physical Medicine has adopted and authorized publication of the following report as a revision of its previous statement "Acceptance of Ultraviolet Lamps for Disinfecting Purposes."[1] HOWARD A. CARTER, *Secretary.*

ACCEPTANCE OF ULTRAVIOLET LAMPS FOR DISINFECTING PURPOSES

PRESENT STATUS

This article represents an analysis of the present status of the proposed use of ultraviolet lamps for disinfecting purposes, indicating the probable degree of effectiveness that may be expected in the various applications, and a recommendation of supervisory organizations (state, county, municipal) under whose purview such uses appears to belong. This analysis is followed by a statement of the Council "Requirements for Acceptance of Ultraviolet Lamps for Disinfecting Air."

In reconsidering the previous statement[1] the Council reaffirmed its decision to accept ultraviolet lamp devices only as adjuvants or supplements to other methods of disinfecting air in hospitals, nurseries and operating rooms, where the population can be controlled.

Perusal of recent advertising literature and reports, issued by manufacturers, indicates that the use of ultraviolet lamps for disinfecting purposes is proposed for a wide range of applications (dairy and poultry industry; irradiation of meat, beverages, etc.) that are outside the purview of the Council on Physical Medicine.

Under the Council's rules the acceptance of any device by the Council may not be used to promote the sale of such device for uses that are not specifically indicated by the Council's acceptance.

Sales promotion for installation of ultraviolet disinfecting lamps, for applications outside the Council's purview, must not include references to applications accepted by the Council.

I. ANALYSIS OF PRESENT STATUS OF ULTRAVIOLET LAMPS FOR DISINFECTING PURPOSES

After due consideration of the present status of the use of ultraviolet radiation as a germicide, in consultation with bacteriologists, physicists, chemists, ventilating engineers and other scientists, the Council on Physical Medicine[1] promulgated its first regulations for acceptance of ultraviolet lamps for use as an adjuvant in the disinfection of air.

It was then noted, and it continues to be true to this day, that a lamp used for disinfecting purposes is a single unit in an installation and that compliance of the ultraviolet output of a single lamp unit with the Council's requirements does not insure adequate radiant disinfection or the safety of the occupants of the room in which an installation of such lamps is in actual use. Obviously the manufacturer and distributor of such lamps, as well as the superintendent of the hospital, must assume some responsibility for the adequacy of the lamp installation for the purposes of radiant disinfection of the air and for the adequacy of the protection from injury of the occupants of the space irradiated. Concerning these questions the Council cannot undertake supervision or assume responsibility for the satisfactory performance of any particular installation. While much progress has been made in protecting the occupants, the most frequent complaint that comes to the attention of the Council is injury by ultraviolet burns and conjunctivitis caused by improperly installed ultraviolet lamp fixtures. The Council therefore recommends that, before occupancy of the beds and cubicles, measurements be made to determine that the ultraviolet intensities do not exceed the values specified in this acceptance.

The total amount of direct and scattered ultraviolet radiation incident on the occupants must be kept below the level that will produce conjunctivitis, erythema and any other injurious physiologic effects that may arise from prolonged irradiation. This requirement should be met by a suitable arrangement of the lamp fixtures and light baffles and not by requiring the occupants of hospital wards and nurseries to wear glasses and a special covering of the parts of the body (face, hands) normally uncovered. Recently the attention of the Council was called to a drying and roughening of the skin of some of the nurses and infants in a nursery (caused by the slow photochemical action of diffusely reflected ultraviolet radiation) that was remedied by painting the walls and ceiling with a decorative, light blue paint that absorbed these rays. The Council's specification of the maximum allowable intensity for continuous exposure to ultraviolet radiation is based on measurements in this nursery after painting the walls and ceiling. Recent developments indicate that reflected ultraviolet intensities in excess of that specified by the Council should be remedied by painting all ordinary and all perforated acoustic ceilings with a standard oil paint or by painting nonperforated acoustic materials with a coat of ordinary glue wall size.

The efficiency of the emission line 2,537A (angstroms) in producing an erythema is very high and, in contrast, the efficiency of this emission line in producing tan is very low.[2] As a result of this slow-acting protective mechanism (tanning, skin pigmentation) the occupant of the room may suffer severe burns.

The data governing the Council's Acceptance of Sun Lamps[3] show that exposure to an intensity of 36 microwatts per square centimeter of radiation of wavelength 2,537A produces an erythema in about fifteen minutes. If the reciprocity law holds for very low intensities and long exposures, then the total intensity of the ultraviolet radiation (diffusely reflected from the walls and fixtures and emanating directly from the lamp) incident on the occupant for seven hours or less should not exceed five-tenths microwatt per square centimeter ($0.5 \mu W/cm.^2$) and for continuous exposure (twenty-four hours a day) should not exceed 0.10 microwatt per square centimeter[4] of wavelength 2,537A. How to design the lamp installation to meet the requirements for adequate disinfection of a room and at the same time protect the occupants is a problem for solution by the sanitary engineer.

At the present juncture the design and installation of ultraviolet lamps in their fixtures for disinfecting purposes is empiric and the adequacy of disinfection by any given installation of lamps must be judged by clinical experience. For example, in connection with the first Acceptance[1] clinical evidence was submitted to the Council showing that, in a scarlet fever ward (size about 60 by 27 by 11 feet) containing sixteen cubicles, four lamp units suspended over the central corridor, each lamp unit emitting a radiant flux of 30 microwatts per square centimeter at 1 meter, were found inadequate; but eight lamp units in the ward, each unit protecting two cubicles, and a ninth unit at the entrance, prevented cross infection. This is a rather high intensity (requiring twenty minutes calculated time to produce a minimum perceptible erythema) incident on a person of average height, standing directly under a lamp fixture suspended from a ceiling of average height.

[2] Luckiesh, Matthew, and Taylor, A. H.: Production of Erythema and Tan by Ultraviolet Energy, J. A. M. A. **112:** 2511 (June 17) 1939.

[3] Acceptance of Sunlamps, J. A. M. A. **102:** 42 (Jan. 6) 1934; **114:** 325 (Jan. 27) 1940.

[4] The accuracy of this value is confirmed by tests recently reported by Anderson, W. T.: Arch. Phys. Med. **28:** 705 (Nov.) 1947.

Experience shows that an ultraviolet lamp, mounted in a fixture that shines downward (a "light curtain") in a corridor, is a potential hazard from burns, especially on the calves and ankles of the attendants. Present day disinfection is principally by irradiation of the upper air of the room with fixtures attached on the side walls, shining crosswise, with minimum intensities incident on the ceiling, involving no direct radiation downward to the face level of the attendants in the room Hence, enough fixtures should be used to provide an average ultraviolet intensity of 20 to 25 microwatts per square centimeter throughout the whole irradiated area to disinfect the area completely in one to two minutes and to maintain an adequate disinfection while the lamps are in operation. This is a matter of engineering design, beyond the Council's purview.

PHYSICAL DATA ON DISINFECTING LAMPS

Experimentally, equal amounts of energy of different wavelengths being applied, it is found that the spectral band at 2,652A appears to produce the maximum bactericidal action and that the emission band at 2,537A is about 75 per cent as effective (on Escherichia coli). This difference in effectiveness is negligible in the present considerations because in readily obtainable sources of germicidal radiation, especially in the low vapor pressure (high voltage) mercury discharge tube, which is well adapted for killing micro-organisms, the ultraviolet radiant power of wavelength 2,652A is less than 0.2 per cent of that of wavelength 2,537A, the resonance emission band that dominates the whole ultraviolet spectrum of this type of lamp. Thus the use of a lamp emitting principally the wavelength 2,652A is impracticable.

Over 90 per cent of the total biologically effective ultraviolet radiation of wavelengths shorter than 3,132A emitted by the low pressure mercury discharge (whether in quartz or in a transparent glass tube) is concentrated in the emission line at 2,537 A. For this reason the emission line at 2,537 A, logically and by common consent, is taken as the standard of homogeneous ultraviolet radiation for evaluating the ultraviolet output of germicidal lamps, just as the wavelength 2,967A in the high vapor pressure (low voltage) mercury arc is taken as the standard of homogeneous ultraviolet erythematogenic and antirachitic radiation in evaluating the ultraviolet output of therapeutic lamps.[3]

The low pressure mercury discharge in a suitable glass tube or in a suitably filter-jacketed quartz tube which readily transmits the strong, highly germicidal emission line at 2,537A but is opaque to wavelengths shorter than about 2,200A (that generate ozone) appears suitable to supplement other means of disinfection when operated under controlled conditions and limited to certain types of applications. In other words, the room must be relatively free from dust and infecting bacteria, without the use of ultraviolet disinfecting lamps. Ultraviolet radiation is not a substitute for cleanliness.

From the evidence available it appears that a minimum of 5,000 to 10,000 microwatt seconds per square centimeter (μW sec./cm.^{2} or 50,000 to 100,000 ergs/cm.^{2}) of homogeneous radiation of wavelength 2,537A is required to produce adequate (practically 100 per cent) killing of micro-organisms, especially bacteria. This value may, perhaps, be lower for air, depending on the amount of dust and suspended droplets. With an exposure of fifty to one hundred seconds this will require an intensity of 100 microwatts per square centimeter.

The Council has adopted 100 microwatts per square centimeter of homogeneous radiation of wavelength 2,537A as the unit of germicidal intensity (G. U.); that is, 1 G. U. = 100 μW/cm.^{2} of radiation of wavelength 2,537A.

Since the ultraviolet emission from the low vapor pressure mercury discharge tube is practically homogeneous radiation of wavelength 2,537A, such a lamp can be readily calibrated in absolute value and used as a standard. As noted in the foregoing, the intensity at 1 meter may be only one fifth of the Council's unit, or 20 microwatts per square centimeter, for safety to the occupants, provided sufficient lamp units are used.

SCOPE OF THE COUNCIL'S ACCEPTANCE OF ULTRAVIOLET LAMPS FOR DISINFECTING PURPOSES

The Council's first specifications of "Acceptance" were promulgated after careful consideration to the feeling, expressed by manufacturers vitally concerned in the matter, that the general acceptance of the use of ultraviolet radiation as a sanitary agent may necessitate some form of regulation and that ultraviolet generating units offered to the public and medical profession may be classed with antiseptic agents requiring a degree of control of their potency and keeping qualities.

In the meantime, apparently to capitalize on the dramatic appeal to the public and in some instances on a liberal interpretation of a limited amount of statistical data, the use of ultraviolet lamps is proposed for a variety of disinfecting purposes far exceeding the purview of the Council on Physical Medicine, and involving consideration by state, county and municipal health boards, sanitary commissions and safety engineers, who can supervise, follow up and enforce their requirements.

It is not the intention of the Council to evade its responsibility, and, as in the past, it intends to report on the possibilities and limitations of devices and procedures offered for healing purposes, including the use of ultraviolet radiation.

The procedure of disinfection by ultraviolet radiation is too new, too complex and apparently too uncertain, where virulent organisms (e. g., typhoid) may be concerned in spreading epidemics, to warrant wide unsupervised use. Moreover, in view of the use that would be made of its "Acceptance" for advertising purposes; also the legal implications involved, and the precedent that would be established in the preparation of serums, blood irradiation, and so on, the Council cannot be expected to accept devices designed for the unrestricted use of ultraviolet radiation for disinfecting purposes where conditions cannot be controlled and where the effectiveness is far below the maximum (100 per cent).

It is understandable why a manufacturer desires to establish the widest possible application of a new device. In the present instance the variety of proposed applications of ultraviolet radiation for disinfecting purposes is unprecedentedly large in comparison with the three medical applications (hospitals, nurseries and operating rooms) that, as will be noted presently, fall within the Council's purview. If the advertising matter issued by a lamp manufacturer and by a lamp fixture manufacturer includes all contemplated applications in one general folder or brochure, the Rules of the Council will be violated because nonaccepted procedures will be advertised with accepted procedures.

Herewith follows an analysis of some of the proposed applications of ultraviolet radiation as a disinfectant and a statement of *the specific applications that appear to fall within* the Council's purview.

In its first "Acceptance"[1] the Council reported the advantages and disadvantages of the use of germicidal ultraviolet radiation for sterilizing purposes which are summarized in the 1941 issue of "The Chemical Action of Ultraviolet Rays," by Ellis and Wells, second edition, by Francis F. Heyroth[5]; also in the researches of Koller,[6] who found that while sterilization of glassware and dishes is possible by means of ultraviolet radiation it was extremely important to start with fairly clean surfaces. Practically the same results are reported in an investigation by Appling and Tanner.[7] This was confirmed at that time in unpublished reports of tests made by the United

States Public Health Service. While these investigators noted decided improvement on irradiation, complete sterilization did not result in every case.

Reference was made also to an editorial on "Disinfection by Light,"[8] showing that much remains to be done in studying the capacity of such lamps to reduce the dangerous bacterial content of the air, not only under controlled laboratory conditions, but also in the more difficult and varied circumstances of practical use. This statement remains true to this day.

In this connection it is important to note that in order to kill a micro-organism a direct hit by ultraviolet rays of sufficient intensity is required. This is difficult to accomplish on the edge of a drinking cup, also in a liquid containing suspended matter or in air laden with dust particles that shield the organism. To provide adequate sterilization a germicide must effect practically 100 per cent killing. Ultraviolet germicidal rays cannot penetrate deeply and hence may be absorbed by finger marks, saliva, cosmetics or other contamination on a drinking cup. The ultraviolet germicide lamp, therefore, appears to be an uncertain means of sterilizing solid objects (drinking cups, combs, brushes, shaving utensils, shoes, toilet seats) even if irradiation of the whole surface is possible.

If ultraviolet germicidal lamps are used to irradiate shelves and housing in which freshly washed eating and drinking utensils, and the like, are stored, then adequate protection is required to prevent ultraviolet burns on the hands and arms of the attendants who manipulate these utensils.

Recent evidence seems to indicate that the ultraviolet germicidal lamp can be used for disinfecting the water used in beverages and the like but only after adequate removal of suspended material; and it is applicable only to liquids which are highly transparent to ultraviolet germicidal radiation. As is to be expected, this irradiation process requires an expert bacteriologist to test the product for purity and freedom of pathogenic organisms.

About three decades ago an elaborate attempt was made to disinfect water, on a large scale, by ultraviolet radiation using hot quartz mercury arc lamps, which, under the conditions of operation, remained relatively cool, and emitted a large amount of germicidal radiation of 2,537A, and longer wavelengths. The presence of suspended matter and the necessity of keeping the surface of the quartz glass covering of the lamps free from slime (algae) made ultraviolet radiation an uncertain method of disinfecting water. Consequently, the proposal to irradiate the water supply of a mountain resort hotel, obtained from springs that became turbid after a freshet, was rejected.

With the advent of the low vapor pressure mercury arc germicidal lamp the proposal has been revived to disinfect, by ultraviolet radiation, the water supply of summer camps and isolated rural communities. This will require a periodic bacterial examination to determine the effectiveness of the irradiation. Evidently this is a task for the board of health, or sanitary commission of the state or county, whose duty it is to check the purity of the water supply. In the light of available evidence the Council is not convinced of the efficacy of this method of disinfecting water.

Although mold spores are difficult to kill by ultraviolet rays, recent reports seem to indicate a reduction in growth of mold by "direct hits" on directly irradiated surfaces of tanks of sugar syrup, walls of bakeries, meat storage rooms and the like. These are commercial applications that financially will solve themselves, or in the case of food and meat storage can be handled best by the inspectors already employed in that service.

Apparently some of these installations are made as a matter of competition. At any rate, in the case of one large meat processing plant, the Council's consultant was informed that no observations had been made on the effectiveness of the ultraviolet lamp installation, presumably for the reason that the product was consumed before it had time to mold.

Another proposal is to use the germicidal lamp for irradiating milk. When this process was first tried out, using arc lamps with impregnated carbon electrodes, it was found that a slight overexposure to ultraviolet radiation produced a disagreeable taste; also that the wavelengths in the range of 2,537A were more effective in causing this bad taste than the wave band of intense radiation, at 2,852A, emitted by the magnesium arc. Evidently if this process of ultraviolet irradiation is adopted in the dairy industry it is incumbent on the state or municipal sanitary commissions to see that the consumer receives a palatable product.

The poultry business is of great economic importance, and the sale of ultraviolet disinfecting lamps is being promoted to reduce the spread of infectious diseases among large flocks of chickens. This is reported possible when there is a regular attendant to service the lamps. On the other hand, there is also a large economic waste and loss of capital when the small scale poultry raiser has not the time or patience to dust off the lamp "every day" to keep it at maximum efficiency, and discontinues its use. In the light of present evidence the Council does not accept the application of disinfecting lamps in the poultry business.

The use of ultraviolet lamps for disinfecting theaters, barracks, industrial plants, assembly halls, waiting rooms, schools, buses for transporting school children, street cars and the like, is on the borderline of applications that the Council is not convinced it should accept without fundamental qualifications that are not enforceable, for the following reasons: (1) because the population cannot be controlled; (2) because of the dramatic appeal to the public that inevitably will lead to exploitation by unscrupulous sales promoters; (3) because of "the futility of trying to stop colds among school children by irradiating only their classrooms[9] and not controlling their surroundings when they are not in the classroom," and (4) because statistical data are so variable. These data indicate that, although ultraviolet radiant disinfection of air can be substituted for actual air displacement in reducing cross infection in chickenpox, measles and mumps,[10] the uncertainty (as measured by the number of absences due to colds) ranges from a negative value (more absences from the irradiated school than from the control school) to definite positive improvement in attendance.

Probably the best controlled observations on reduction of cross infection were obtained at the U. S. Naval Training Center, Camp Sampson, N. Y., where observations were made on large groups of recruits housed in barracks as follows: (1) barracks irradiated with high intensity germicidal lamps; (2) alternate barracks having low intensity germicidal lamps, and (3) barracks used as controls in which there were no germicidal lamps.

The results of this investigation,[11] which extended over a period of six months (December to May) are impressive and instructive in showing that the incidence of respiratory illness in the barracks irradiated with low intensity ultraviolet lamps followed the same undulations that occurred in the adjacent control barracks, whereas in the barracks irradiated with a high intensity there was a definite reduction in the incidence of respiratory illness—a reduction estimated at 25 per cent for the entire period of observation of respiratory illness in the high intensity irradiated group as compared with the control group, "and not due to chance." These data are confirmed in a prolonged series of observations, during the winter of 1945-1946, at the Great Lakes Naval Training Center.[12] In this report data are given showing that ultraviolet irradiation of the floors and upper air in barracks, housing recruits, resulted in a 19.2 over-all reduction in total respiratory disease. Considering streptococcus disease (scarlet fever plus tonsillitis and pharyngitis having strongly positive throat cultures), a 24 per cent reduction in the incidence of disease was observed in the radiated group.

In the opinion of the authors of this report[12] the results of their studies do not warrant the general application of ultraviolet radiation for control of air-borne infection in barracks.

An average reduction of 25 per cent in respiratory infection seems to be a conservative estimate of the effectiveness that can be expected of ultraviolet irradiation. In this connection it is relevant to cite a recent report issued by the New York State Department of Health,[13] which states that ultraviolet radiation seemed to have a definite effect in modifying the spread of measles in the classrooms. However, on the basis of these observations the authors state specifically that they are not recommending routine installation of ultraviolet lamps in classrooms.

A good illustration of the difficulty of preventing possible cross infection among children is a recent instance in which several kindergarten children shared their much-chewed "bubble-gum" (which in itself rapidly becomes an unsanitary material) with a child who was not permitted to have such gum.

Evidently the existing state and municipal health and sanitary commissions, staffed with competent, financially disinterested personnel and vested with legal authority to enforce safety regulations, are the proper authorities to consider these proposed applications of ultraviolet disinfection.

II. REQUIREMENTS FOR ACCEPTANCE OF ULTRAVIOLET LAMPS FOR DISINFECTING AIR

On the basis of the foregoing considerations the Council on Physical Medicine has decided to continue its previously announced policy[1] of accepting ultraviolet lamps, as an adjuvant, for disinfecting air in hospitals, nurseries and operating rooms (relatively free from dust) as practiced by present day empiric methods.

Clinical evidence submitted to the Council shows that under properly controlled conditions killing of air-borne micro-organisms by ultraviolet rays may be used to supplement other methods of disinfecting air for prevention of cross infection in contagious wards in nurseries and hospitals and for reducing air-borne infection of wounds in operating rooms. The deleterious effects of ozone generated by ultraviolet lamps are recognized. The Council therefore requires for acceptability of ultraviolet disinfecting lamps that, under suitable ventilation, in the space near the occupants of the room the concentration of ozone shall not exceed 1 part in 10,000,000.[14] However, in view of the recent researches by Witheridge and Yaglou[15] showing that a much lower concentration (1 part in 25,000,000) is irritating to the mucous membranes of the upper respiratory tract, this specification of 1 part in 10,000,000 is tentative, awaiting confirmation of the evidence that a lower concentration of ozone is desirable in nurseries and hospital rooms occupied twenty-four hours a day. If the odor of ozone is distinctly perceptible the Council recommends increased ventilation.

Recently manufacturers have determined on the manufacture of two kinds of ultraviolet disinfecting lamps: (1) the type "L" lamp that generates a low amount of ozone and (2) the type "H" lamp that produces a high amount of ozone. The Council accepts only the type "L" lamp, that generates practically no ozone.

In considering ultraviolet generators for disinfecting purposes the Council makes no distinction between lamps for use in air conditioning ducts and lamps for use in open rooms in which there is only a slow circulation of air. In both cases a sufficient number of lamps must be provided to insure adequate disinfection of the air as determined by approved culture tests or other accepted procedures. So that an ultraviolet output above the minimum value for adequate disinfection may be maintained, the Council recommends that the ultraviolet intensity of each lamp unit be measured at least once a month.

To comply with the Council's requirements the ultraviolet spectral energy distribution of the disinfecting lamp shall be comparable in lethal effectiveness with the low vapor pressure mercury discharge tube, in which the dominant radiation is of wavelength 2,537A.

The minimum intensity at right angles to and at a distance of 1 meter from the plane of the lamp tube in its fixture shall not be less than the germicidal equivalent of 20 microwatts per square centimeter of homogeneous radiation of wavelength 2,537A. The useful life of the lamp shall not be less than four thousand hours. During this period the ultraviolet output shall not fall below the herein specified minimum intensity. To meet this requirement the lamp may be provided with a voltage regulator to compensate for the decrease in intensity of ultraviolet with usage; or the lamp may emit a sufficient excess of ultraviolet radiation when new, so that the output shall not fall below the specified minimum value (20 μW/cm.^{2} at 1 meter) in less than four thousand hours' operation. In either case the installation shall be provided with adequate safeguards against overexposure of the occupants of the room to ultraviolet radiation. The burner of the lamp shall be of glass or of suitably filter jacketed quartz, highly transparent to the emission line at 2,537A, and opaque to radiation of wavelengths shorter than 2,200A, to prevent the generation of an injurious amount of ozone, largely produced by these short wavelengths. To insure compliance with these requirements the lamp may consist of one, two or three tubes, mounted and operated as a unit.

For consideration of acceptance by the Council, the manufacturer shall submit a lamp unit in its fixture, permanently marked as to its useful life, and its radiant flux in microwatts per square centimeter of wavelength 2,537A, at 1 meter under the normal power input used to insure a useful life of not less than four thousand hours. *In addition the manufacturer* shall submit satisfactory clinical evidence, obtained over a period of not less than four winter months, of the effectiveness of an installation of such lamps in maintaining adequately sterilized conditions in the space (hospital, nursery) subjected to radiant disinfection.

Council on Foods and Nutrition

The following statement concerning the potential health hazards of pesticides has been approved for publication by the Council on Foods and Nutrition.

JAMES R. WILSON, M.D., *Secretary.*

HEALTH HAZARDS OF PESTICIDES

The Council on Foods and Nutrition of the American Medical Association is acutely aware of the toxicologic problems presented by the rapid introduction of synthetic organic pesticides and herbicides. The chemical contamination of foods with residues of these substances is but a part of the broader problem created by their wide use, for in addition to the danger from ingestion, the effects of inhalation and skin absorption must be determined.

The problem is created by the great number of new pesticides on the market. The appearance of these is creating an increasing volume of inquiries at Association headquarters. That danger exists is evidenced by the appalling lack of factual data concerning the effect of these substances when ingested with food. The chronic toxicity to man of most of the newer insecticides is entirely unexplored. In fact the majority are so new that their limitations and even their full scope of usefulness have not been established.

The Council recognizes the potential usefulness of newly developed pesticides and herbicides. At the same time it recognizes also the potential hazards to individual and public health of the unrestricted use of pesticides and herbicides which are placed on the open market before they have been adequately studied and their toxicologic properties determined. It is obvious that controls must be placed on the sale and distribution of products of unknown or incompletely known toxicity. The time to establish controls, voluntarily or otherwise, is now, before possible tragic consequences occur. The Council urges, therefore, that measures be taken immediately to insure adequate protection of the public.

ALLEGED CANCER BIOTHERAPY

Roskin[1] and his associates of the University of Moscow have claimed that Trypanosoma cruzi, the causative agent of Chagas' disease, is positively cancerotropic. When injected into normal animals the trypanosomes multiply in the heart, spleen, liver, bone marrow and lymph nodes. In animals with malignant growth, however, the trypanosomes, they assert, are absent from these organs and are concentrated solely in the neoplasm. Thus localized the trypanosomes destroy the malignant growth, presumably caused by the formation or liberation of a specific cancerolytic substance. The Soviet biologists say that this cancerolysin can be extracted from artificial cultures of trypanosomes and is an effective cure for human cancer.

The trypanosome extract was tested on 18 patients with cancer of breast, larynx, uterus or lips. Destruction of the tumor, the Soviet investigators assert, was noted in 11 patients after daily subcutaneous injections of relatively large doses. In some cases softening and shrinking of the tumor was noted within eight days after the first injection. Healthy granulation appeared where the tumor sloughed. Recurrence was not observed in any one of the 11 successful cases.

These encouraging results have been received with skepticism by American investigtators caused by failure to confirm the basic experimental evidence underlying the alleged clinical victory. For example, Cohen[2] and his associates, of the California Institute of Technology, exposed thin slices of mouse carcinoma tissues to trypanosome extracts prepared according to the Soviet technic. Control tests were made with thin liver slices. Demonstrable carcinolytic effects were not noted microscopically. Specific carcinolysins, however, were demonstrated in parallel tests with certain bacterial filtrates (e.g., Sporosarcina ureae and Aspergillus fumigatus).

More detailed tests are currently reported by Hauschka and Goodwin[3] of the Institute for Cancer Research, Philadelphia. Eight different strains of T. cruzi were tested against five varieties of spontaneous and transplanted malignant tumors in over 1,000 experimental mice. The trypanosomes tested included all strains used by the Soviet investigators.

In their hands infection of the tumor mice with the more virulent T. cruzi strains resulted in a consistent inhibition of the tumor growth, but generally did not lengthen the life of cancer mice beyond that of untreated controls. In all cases tumor inhibition was accompanied by a loss of body weight, the weight loss being closely correlated with the virulence of the strain.

Hauschka found no evidence that any one of the eight strains was "positively tumerotropic," as claimed by the Soviet investigators. Injected into cancerous mice, the trypanosomes were only lightly present in the malignant growth, but were heavily concentrated in heart, liver, spleen, kidneys, small intestines and skeletal muscles, as in normal mice. From this the Philadelphia workers conclude that tumor inhibition by living T. cruzi does not appear to be due to an elective localization in the cancerous tissues, but to a general depletion of the host due to the infection. When the infection is checked by drugging with quinoline, the previously inhibited tumor resumes its usual growth rate, and the host eventually dies of cancer.

Culture lysates tested against cancerous mice gave no signs of an inhibiting or cancerolytic effect, and did not prolong life. Death among the treated mice was often sooner than among the untreated controls. From these negative results the Philadelphia investigators conclude that the alleged "endotoxin" of T. cruzi does not at present hold out much promise in practical clinical therapy.

PESTICIDES: CHEMICAL CONTAMINANTS OF FOODS

The development and use of new pesticides and herbicides have created public health hazards. Studies indicate that already many constituents of the American diet may be contaminated with materials of unknown toxicity used to destroy insect pests or weeds.

The insecticides include those materials which have been long in use such as lead arsenate, nicotine and fluorine compounds, and new materials, about which little is known, such as the organic phosphates, chlordan and many others, and DDT, which is probably intermediate between the other two.

The brands of new insecticides, fungicides and herbicides (weed killers), now on the market or contemplated, number several thousand. The rapidity with which this industry has added new basic materials since the introduction of DDT is phenomenal.

[2] Cohen, A. L.; Borsook, H., and Dubnoff, J. W.: Proc. Soc. Exper. Biol. & Med. 66: 440. 1947.

[3] Hauschka, T. S., and Goodwin, M. B.: Science **107**: 600 (June) 1948.

The Council on Pharmacy and Chemistry and the Council on Foods and Nutrition are deeply concerned over this situation because so little is known about either the acute or chronic pathologic effects on man of these new pesticides. At its recent meeting the Council on Foods and Nutrition recognized the potential values inherent in effective pesticides. At the same time the Council recognized the health hazards involved in premature or careless use[1] of toxic substances.

When pesticides are poisonous to insects they are usually poisonous to man.[2] Their true value depends on a significant difference between the toxic effect on man and on insects. Even with this differential the amount ingested by man must be kept at a minimum. These toxic materials are potentially dangerous to those who come into direct contact with them as well as those who ingest the residues which remain on and in foods after their use in the fields. Some of the new poisons are difficult to remove; others are incorporated in the plant tissues and cannot be removed. The latter are particularly insidious.

Voluntary control by the producers and distributors of these substances should be instituted immediately. If voluntary control proves to be inadequate for the protection of the public, suitable legislation must be considered and effective means of control promptly established. At present governmental agencies find it difficult to protect the public from this potential hazard; existing agencies seem to doubt their authority and lack the funds to establish control. Prompt voluntary action by the industry is therefore imperative. The effectiveness of this action will determine the degree of governmental control ultimately required.

At a recent meeting of the Council on Foods and Nutrition the importance of the development of analytical methods for the detection of chemical contaminants was emphasized. This applies both to the whole molecule and to its degradation products. Important is the detection of the presence of pesticide residues by practical methods in fresh as well as in processed foods. The metabolism of insecticide residues and their acute and chronic pathologic effects on mammals must also be determined. Even though added controls may impede the development of pesticides, these are essential precautions which must be taken in order to avoid the danger of mass poisoning, which might well offset the potential benefits of the new agents.

The recognition of the toxicologic problems presented by the contamination of foods and beverages through the use of materials for the purpose of combating pests or the use of chemical technologic aids for improving the appearance, texture, flavor or lasting qualities of foods may well be the beginning of a new era in the science of foods and nutrition. The medical profession has long recognized that food must be free from bacterial contamination and that food must contain essential nutrients and be made to retain them in high degree during processing. Now physicians ask that foods be free from toxic residues of pesticides or other chemical technologic aids.

Current Comment

NOMENCLATURE OF BLOOD

A committee for clarification of the nomenclature of cells and diseases of the blood and blood-forming organs sponsored by the American Society of Clinical Pathologists and the American Medical Association has been functioning since October 1947.[1] The chairman is Dr. Edwin E. Osgood, chief of the Division of Experimental Medicine at the University of Oregon Medical School. The membership is composed of outstanding hematologists from all sections of the United States, including special representatives of the sponsoring societies. The committee has held three meetings, two in Chicago and one in San Francisco, and plans a fourth meeting in Buffalo during August. It has been agreed that the choice of preferred terms will not be based merely on historical priority or common usage but in general, should represent the simplest, clearest and most descriptive term possible. Consistency between related terms is considered essential. The committee has given detailed consideration to terminology in the erythrocytic, lymphocytic, granulocytic, monocytic, plasmocytic and thrombocytic series of cells. Agreements reached by those attending committee meetings are submitted to a wide group of committee members for final agreement. The committee has coordinated its work and cooperated with representatives of the American Medical Association Standard Nomenclature of Disease and Operations, in order that proposed changes may be incorporated in the new edition of Standard Nomenclature. In view of the confusion in hematologic terminology members of this committee have done excellent work so far in this field. Beneficial results might be expected from similar efforts in other medical fields where confusion of terminology exists.

ORGANIZATION SECTION

Official Notes

REVIEWS OF MEDICAL MOTION PICTURES

The Committee on Medical Motion Pictures has prepared a booklet containing all of the Medical Motion Picture reviews published in THE JOURNAL, through Jan. 17, 1948. The purpose of these reviews is to provide a brief description and evaluation of motion pictures which are available to the medical profession. Each film is reviewed by competent authorities. This is *not* a list of films approved by the American Medical Association. One copy has been mailed to the secretary of each county and state medical society. Additional copies are available on request.

Washington Letter

(From Our Regular Correspondent)

Aug. 18, 1948.

Food and Drug Administration Issues Suppository Warning

A joint warning that some "nembutal" (pentobarbital sodium) suppositories manufactured before October 1947 contain from 40 to 223 per cent of the labeled amount of "nembutal" has been issued by the Food and Drug Administration and Abbott Laboratories. Untoward reactions were first reported nine months ago, but the Food and Drug Administration learned only recently that Abbott Laboratories, the manufacturer, had begun to recall those stocks of "nembutal" suppositories which are suspect. Accordingly, physicians, hospitals, druggists and consumers possessing any bearing the code number 710 T 292 or any smaller code number have been urged to return them to Abbott Laboratories, North Chicago, Ill. Suppositories with higher code numbers, or without the letter T, are not being recalled.

Health and Science Legislation Hearings in Print

Volume 4 of the Congressional hearings held in 1947-1948 on the Taft and the Murray-Wagner-Dingell national health bills are now in print. The latest volume is devoted to testimony presented to the health subcommittee of the Senate Labor and Public Welfare Committee by I. S. Falk, director, and Wilbur J. Cohen, assistant director, of the Bureau of Research and Statistics in Social Security Administration, and Dr. Maurice H. Friedman, a Washington physician. In addition, volume 4 contains a large quantity of documentary material entered in the lengthy record by witnesses and members of the committee. Another new publication is the printed transcript of a one day hearing held June 1, 1948, by the House Committee on Interstate and Foreign Commerce on National Science Foundation legislation. It contains statements by eight witnesses, the majority of whom supported establishment of a National Science Foundation.

Veterans Administration Planning Internship Program

Straight and rotating internships will be offered in Veterans Administration hospitals under the new training program recently authorized by Congress. Although the hospitals have not yet been designated and details are still unsettled, pending results of surveys now in progress, it has been decided that: (1) intern training will not be instituted in nonresidency hospitals; (2) adequate living quarters for interns will be a prerequisite, and (3) supervision will be by deans' committees. Annual pay will not exceed $1,800 a year, with quarters, subsistence and laundry to be furnished. Appointments will be made once each year, in accordance with the practice of medical schools and hospitals in general.

Dr. Overholser Heads Delegation to London

The Department of State announces that the United States delegation to the International Congress on Mental Health in London August 11-21 consists of chairman, Dr. Winfred Overholser, superintendent of St. Elizabeth's Hospital, Washington, D. C.; Ruth Adams, head of community nursing, Veterans Administration; Col. John M. Caldwell Jr., chief, neuropsychiatric consultants' division, Army Medical Department; Dr. Martha Eliot, associate chief, Children's Bureau; Dr. Robert Felix, head, mental hygiene division, U. S. Public Health Service; Capt. Frederick L. McDaniel, chief, professional division, Navy Bureau of Medicine and Surgery; Mary E. Switzer, assistant to the Administrator, Federal Security Agency, and Dr. Harvey J. Tompkins, chief, neuropsychiatry division, Veterans Administration, Department of Medicine and Surgery.

Food Intake of Urban Germans Held Inadequate

German urbanites in the American and British zones are not getting enough to eat, according to a report released by Tracy S. Voorhees, Assistant Secretary of the Army. A study was conducted last spring by a special mission comprising Dr. Leonard A. Scheele, Surgeon General, U. S. Public Health Service; Maj. Gen. Raymond W. Bliss, Surgeon General of the Army; Dr. John B. Youmans, dean, University of Illinois College of Medicine, and others. Farmers and rural dwellers are, in general, as well nourished as before the war, said the report, but inhabitants of cities have an average per capita intake of 2,200 calories, whereas it should be 2,540. It was noted that the German male population in the 20 to 39 age group averaged 132 pounds (59.9 Kg.) in body weight, compared with a minimum desirable weight of 148 pounds (67.1 Kg.).

Water Pollution Control Policies Adopted

Officials of Federal Works Agency and Federal Security Agency, including the Surgeon General of the U. S. Public Health Service, have agreed on general operational policies in carrying out the national water pollution control program recently enacted by Congress. The necessary appropriations will be requested of Congress in January. Federal authorities estimate that full participation by the various states in the huge program would entail, among other things, construction of sewerage systems and sewage disposal plants costing more than $3,000,000,000. The U. S. Public Health Service will operate its part of the project from fourteen field offices and the Federal Works Agency from nine divisional offices.

Pan American Medical Supply Agency Launched

The newly established medical supply division of Pan American Sanitary Bureau has been all but swamped in its first weeks of operation. By August 12 steps had been taken toward handling an estimated $3,000,000 in business, according to Leslie Atkins, head of the division, which is under general supervision of Dr. Fred L. Soper, director of the bureau. The bureau's procurement branch acts as a central service agency to the twenty Latin American republics desiring to purchase drugs, medical and surgical supplies, sanitary equipment, etc., in the United States.

V. A. Authorizes Release of Medical Data

A new technical bulletin by the Veterans Administration states: "Data as to the physical or mental condition of claimants or beneficiaries of the V. A. may be disclosed to the responsible officials of federal agencies and state, county and city health departments upon request, without obtaining prior consent of the claimants or beneficiaries. Information so supplied will be marked 'Confidential, official use only.'"

GOVERNMENT SERVICES

ARMY

RESIDENT TRAINING PROGRAM

The Surgeon General's Office announces that applications for the Military Resident Training Program in Army General Hospitals are being received in the Office of the Surgeon General. Under this training program any physician who qualifies for and accepts a commission in the Regular Army Medical Corps will be given the opportunity of competing for an approved residency in the field of his choice.

The specialty training available for newly commissioned officers under this program is as follows:

1. Senior residencies in thoracic surgery, orthopedics, pulmonary diseases, pathology, ophthalmology and physical medicine.

2. Residencies in orthopedics, pathology and physical medicine.

3. Assistant residencies in obstetrics, urology, thoracic surgery, dermatology, pediatrics, anesthesia, general surgery, orthopedics, internal medicine, psychiatry, pathology, ophthalmology, otolaryngology, radiology, physical medicine and clinical physicians' training.

Officers who are not selected to enter residency training on January 1, or July 1, 1949, will, if qualified, be furnished a certificate indicating the date on which they will enter approved professional training. The program is designed to insure that all qualified applicants will be given the opportunity of completing their requirements for certification by an American specialty board.

Oct. 1, 1949, has been established as the deadline for receipt of applications from physicians who are interested in participating in this program. Application blanks may be obtained by writing to the Surgeon General, Department of the Army, Washington 25, D. C.

ACTIVE DUTY FOR RESERVE OFFICERS

The Surgeon General on June 26 invited seven hundred medical service officers to fill openings for active tours of duty. New regulations permit reserve officers to be called for voluntary three year tours in the highest grade they held prior to processing for separation, up to lieutenant colonel. Under the Reserve Retirement Act, reserve officers will receive credit for retirement pay of 2½ per cent of base pay of their highest rank for each year of active service and ½ per cent for each year of inactive service. The classes of reserve officers most needed are biochemists, sanitary engineers, physiologists, psychologists, serologists and nutritionists. Age-in-grade restrictions have been removed so that officers beyond the usual age maximum for their rank are eligible for active duty; those under 30 years of age may apply for competitive tours of duty for commissioning in the Regular Army.

AWARDS AND COMMENDATIONS

Brigadier General Leon A. Fox

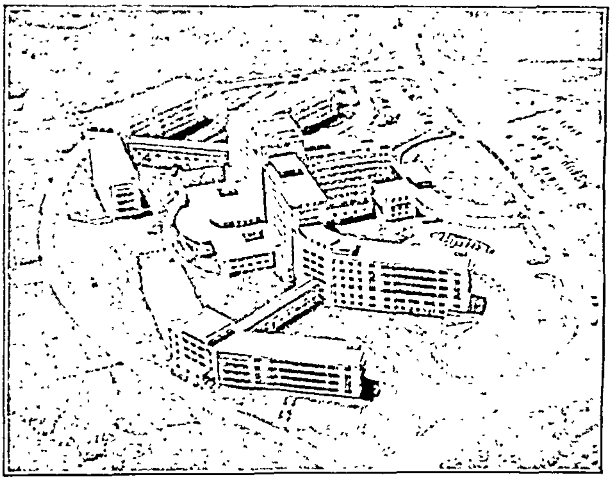
At a ceremony July 22 Brigadier General Leon A. Fox, United States Army, Retired, was decorated by the British Ambassador as an Honorary Commander of the Order of the British Empire. The citation read in part as follows: General Fox, as Field Director of the United States of America Typhus Commission, rendered most valuable assistance to the British Armies. The benefit of his advice and the services of the Typhus Commission were placed at our disposal, and the whole weight of his support was lent to reinforce our bids for supplies. When we were faced with the biggest typhus epidemic of modern times in Western Europe, it was, in no small measure, due to his help that we were able to successfully prevent an outbreak, which might have been devastating. His frequent visits to the 21st Army Group were of inestimable value in planning our antityphus campaign and, later, in the control of typhus. His help was a vital factor in controlling the spread of epidemic typhus in the British Zone.

MEDICAL CONSULTANTS IN JAPAN

General Headquarters, Far East Command, reports as of July 15 that five American medical consultants arrived in the Far East for a thirty day tour during which they will confer with medical officers in the field. The consultants are Drs Carlton N. Price, obstetrics and gynecology, Washington, D. C.; George C. Griffith, cardiology, Los Angeles; John M. Cotton, psychiatry, Ithaca, N. Y.; Clarence H. Snyder, orthopedic surgery, Grand Rapids, Mich., and Amos R. Koontz, surgery, Baltimore. They will visit Army hospitals throughout Japan, Korea and the Ryukyus Command, making ward visits, holding clinics and lecturing on the latest practices in medicine and surgery.

DEDICATE NEW TRIPLER HOSPITAL

Army officials announce that the new Tripler General Hospital on Moanalua Ridge in Honolulu, Hawaii, will be dedicated September 10 at a formal ceremony to which the public will be invited and will include an "open house" tour of the fifteen hundred bed hospital. The new Tripler will replace the 147th General Hospital, long familiar to Honolulans as "Old Tripler," opposite Fort Shafter. Prominent civilian and military officials and representatives of Hawaii's business and community life will participate in the ceremony marking the end of a four year period which began July 18, 1944, when Army engineers undertook the construction of this the newest and finest in the Army's hospital system.



Aerial view of Tripler General Hospital.

RESERVE NURSES AND RETIREMENT BENEFITS

Women officers of the Army Nurse Corps Reserve are eligible now for reserve retirement benefits under provisions of a law enacted by the 80th Congress. Retirement pay is at the rate of 2½ per cent of the pay of the highest rank held during the period of service, multiplied by the number of years of satisfactory service. After twenty years of satisfactory service, an Army nurse may discontinue her active participation in reserve affairs and still qualify for retirement at 60, or she may continue earning qualifying points until she reaches the age of 60, and retire at a higher rate up to 75 per cent of her base and longevity pay. The standards of satisfactory service as a reservist require that 50 qualifying points be accrued each year. Points may be earned by extended active duty, by short periods of active duty training, attendance at drills, and by membership in the Officers' Reserve Corps. Thus, even nurses who remain in civilian life and do not request extended active duty may accumulate points toward retirement.

NAVY

PERMANENT APPOINTMENT OF RESERVE OFFICERS

On June 3, 1948, the Secretary of the Navy, for, and in the name of, the President, appointed officers of the Naval Reserve to permanent grades. Naval Reserve Medical Officers listed, have by virtue of their permanent appointment, the same grade as their contemporaries in the Regular Navy.

To effect his appointment, each officer is required to have in his possession, suitable identification and positive evidence that he received a Certificate of Satisfactory Service if he has been released from active duty. He must also make a certified statement as to his physical condition and take a physical examination, if appropriate.

Public Law 305—79th Congress, approved Feb. 21, 1946, provides that Naval Reserve officers shall have on their return to an inactive status the highest grades and ranks in which, as determined by the Secretary of the Navy, they served satisfactorily under temporary appointments.

Any officer who does not desire to accept the appointment authorized shall submit a statement to that effect to the Chief of Naval Personnel via the Commandant of the appropriate Naval District, stating the reasons therefor and whether or not he (or she) desires to continue in the status of an officer of the Naval Reserve.

RESERVE OFFICERS ON ACTIVE DUTY

Lieuts. (jg) Paul S. Bamberg, Boston; Robert M. Hamill, Holyoke, Mass., and Earl R. Peters, Fort Blackmore, Va., Medical Corps Reserve officers, have volunteered for one year of active duty after completing their internships at the Naval Hospital, Chelsea, Md.

The following Medical Corps Reserve officers have been nominated for their first duty: Lieuts. (jg) William J. Browning III, Merchantsville, N. J.; Joseph J. Goralka, Chicago; Burton Hall, Omaha, Neb., and Duncan O. Montgomery, Corpus Christi, Texas.

POSTGRADUATE INSTRUCTION

The following additional medical officers have been nominated to attend courses of postgraduate instruction at the institutions indicated: Comdr. Melville M. Driskell, cardiology, Massachusetts General Hospital, Boston; Comdr. Robert S. Poos, preventive medicine, University of California School of Public Health, Berkeley; Comdr. William S. Wray, pediatrics, Naval Hospital, Chelsea, Mass.; Lieut. Comdr. Elmer R. King, radiological defense, Duke University, Durham, N. C.; Lieut. Herbert G. Stoecklein, dermatology and syphilology, Naval Hospital, San Diego, Calif.; Lieut. (jg) Frederick A. Clark Jr., internal medicine, Naval Hospital, San Diego, Calif.; Lieut. Richard S. Farr, radiation effects on hematopoiesis, University of Chicago; Lieut. (jg) James R. Hamilton, dermatology and syphilology, Naval Hospital, San Diego, Calif.; Lieut. (jg) Verne K. Harvey Jr., preventive medicine, University of California School of Public Health, Berkeley, and Lieut. (jg) Robert L. Hill, internal medicine, Naval Hospital, Long Beach, Calif. Lieut. Comdr. Harold R. Scanlin, residency in surgery, Naval Hospital, Long Beach, Calif.; Lieut. Gerald E. Wineinger, residency in otolaryngology, Naval Hospital, San Diego, Calif., and Lieut (jg) Harry C. Nordstrom, instruction in aviation medicine, Naval School of Aviation Medicine and Research, Pensacola, Fla.

SPECIALISTS IN THE NAVY

The Surgeon General announces that the following medical officers were recently certified by the American Specialty Boards, bringing the total number of certified specialists in the Navy to 155: Comdr. Lawrence L. Bean (surgery); Capt. Earl F. Evans (internal medicine); Capt. Herman A. Gross (surgery); Capt. Thomas G. Hays (surgery); Comdr. Harold Hirshland (obstetrics and gynecology); Comdr. Dunne W. Kirby (internal medicine); Capt. Edward P. Madden (obstetrics and gynecology); Comdr. George L. Tabor Jr. (ophthalmology); Lieut. Comdr. Samuel V. Thompson (psychiatry and neurology), and Lieut. (jg) John R. Carter (pathology).

CERTIFICATE OF ACHIEVEMENT

The Surgeon General's certificate of achievement was presented in August to the Holy Name College, Franciscan House of Studies, Catholic University of America, in a ceremony at the Naval Hospital, Bethesda, Md.. Capt. L. O. Stone, Commandant of the Hospital, made the presentation to Father Alban Maguire in recognition of outstanding services rendered to the Medical Department of the Navy during and immediately following the war years. The students assisted the Navy chaplains at the Naval Hospital with choir and religious services and were generous in making contributions to the blood bank.

PERSONAL

Comdr. Vernon E. Martens of St. Louis, Lieut. Walter H. Jarvis of Grand Saline, Texas, and Lieut. (jg) William E. Carter of Memphis, Tenn., have transferred from an active Reserve status to the Regular Navy Medical Corps.

MISCELLANEOUS

INDIAN SERVICE NEEDS PHYSICIANS

The Department of the Interior announces a reopening of a civil service examination for medical officer for service with the American Indians. No written examination on professional subjects is required. The examination consists of registration of credentials and supported statements as to qualifications and experience. Most of the Indian reservations where physicians are employed are located in states west of the Mississippi River. The 400,000 Indians in the United States and 30,000 Eskimos, Indians and Aleuts in Alaska who are beneficiaries of this service offer a variety of clinical material. The medical officer serves as the family physician and public health advisor and participates in the administration of small well equipped hospitals, of which the Indian Service operates sixty-six in the states and eight in Alaska. There are also some larger medical centers. The entrance salary is $5,232 or $6,235.20 per annum, depending on the qualifications of the applicant. An automobile is furnished for official use, annual educational and sick leave are provided, and the provisions of the United States Employment Compensation Commission Act and retirement apply. Information may be obtained from Dr. Ralph B. Snavely, Office of Indian Affairs, New Interior Building, Washington 25, D. C.

COURSE IN TECHNICS OF USING RADIOISOTOPES

The second four week course in the technics of using radioisotopes in research began August 2 at the Oak Ridge Institute of Nuclear Studies, Inc., Oak Ridge, Tenn. The institute, which is comprised of nineteen Southern universities, conducts a program of research and training in the nuclear sciences. Radioisotope training courses are under the direction of Dr. Ralph T. Overman, acting head of the Special Training Division of the institute, and the instructors are from various universities throughout the country. With these courses, leaders in the atomic energy field are conducting seminars and demonstrations, and the Oak Ridge National Laboratory, the center of radioisotope production for the Atomic Energy Commission, is assisting the institute in this activity. The current course in the technics of using radioisotopes is being attended by thirty-two members of the staffs of various universities, some as far west as Oregon and others as far east as Columbia University, New York. The staff members attending this course will have an important role in training future leaders in the medical aspects of atomic energy.

Medical News

(Physicians will confer a favor by sending for this department items of news of general interest: such as relate to society activities, new hospitals, education and public health. Programs should be received at least two weeks before the date of meeting.)

CALIFORNIA

Appoint Assistant Dean.—Dr. John C. Talbot, assistant professor of preventive medicine, University of California Medical School, Berkeley-San Francisco, has been appointed assistant dean of the school, adding duties as chief premedical adviser. Dr. Talbot is a graduate of the university, 1939, and, after service in the Army Medical Corps, joined the staff of the medical school in 1946.

Plague in Ground Squirrels.—The U. S. Public Health Service reported plague infection proved under date of June 22 in pools of fleas from ground squirrels, Citellus beecheyi, taken in San Luis Obispo County as follows: Proved June 18, a pool of 172 fleas from 31 ground squirrels shot at Salinas Dam area (United States Reservation), 4 miles east and 2½ miles south of Santa Margarita; proved June 21, a pool of 58 fleas from 11 ground squirrels shot 3 miles west of Pozo on State Highway 178, and a pool of 207 fleas from 19 ground squirrels shot on a ranch on Pozo Road 2 miles east and 1 mile south of Santa Margarita.

Police Protection for Night Calls.—The Los Angeles Medical Association has made an agreement with the Los Angeles Police Department whereby police protection will be given to any physician when the physician deems such protection necessary. The doctor on emergency call will register the call with the Los Angeles Medical Exchange and call the police department, giving the address of the emergency call and the time that he expects to arrive there. The police department will dispatch a patrol car to the address, and the policeman will remain on duty until he is dismissed by the attending physician. Each branch of the association is compiling a list of doctors who are willing to make emergency calls in their respective communities.

COLORADO

Harvey Sethman Awarded Medal.—At the commencement exercises of the University of Colorado in Denver in June, the University's annual medal for outstanding public service was awarded to Harvey T. Sethman, Executive Secretary of the Colorado State Medical Society. Mr. Sethman, who has served the state society for nineteen years, is also managing editor of the *Rocky Mountain Medical Journal.*

Annual State Medical Meeting.—The annual session of the Colorado State Medical Society will be held at the Hotel Colorado, Glenwood Springs, September 22-25, under the presidency of Dr. John S. Bouslog, Denver. The scientific sessions beginning September 23 include the following guest speakers:

Francis H. Wright, Chicago, Purulent Meningitis in Childhood.
Ferdinand R. Schemm, Great Falls, Mont., Quantitative Requirements for Water of Seriously Ill Patients with Heart and Kidney Disease.
George F. Lull, Chicago, Secretary and General Manager, American Medical Association.
Henry W. Woltman, Rochester, Minn., Differential Diagnosis of Poliomyelitis.
Edward B. D. Neuhauser, Boston, Surgical Lesions in Childhood.
Louis Schwartz, Washington, D. C., Diagnosis and Treatment of Occupation Dermatitis.

Sports events will take place Wednesday afternoon and evening. At the joint meeting of the society and its auxiliary Friday evening Dr. Dwight Murray, Napa, Calif., member of the Board of Trustees of the American Medical Association, will speak. The banquet is scheduled for Saturday evening.

FLORIDA

Narcotic Violation.—The Bureau of Narcotics, Washington, D. C., reports that Dr. Dan E. Hardie, Miami, pleaded guilty to violation of the federal narcotic law and on May 11 was placed on probation for a period of five years.

New Public Health Workers.—Five new physicians have joined the ranks of public health personnel in Florida and will be assigned as health officers in counties where vacancies exist, or as assistant health officers. They are: Drs. Joseph H. Batsche, Cincinnati; Albert O. Ryan, Covington, Ky.; Maurice M. Hall, New Orleans; Charles O. Parker, Waycross, Ga., and Holland M. Carter, Greenville, S. C.

Tuberculosis Program Progress.—Since the Florida Tuberculosis Board, the Florida Tuberculosis and Health Association and the state health department coordinated their tuberculosis programs nine months ago, the number of roentgenograms of the chest taken has almost doubled. From October 1947 to June of this year, more than 300,000 persons were given roentgen examinations as compared to 155,763 during the first nine months of last year.

ILLINOIS

Dr. Grulee Presents Collection to Library.—Dr. Clifford G. Grulee, Evanston, has given his collection of books, periodicals and letters on children's diseases to John Crerar Library in Chicago. It includes nearly 5,000 books, including a fifteenth century book, the first on child diseases ever printed, besides fifteen books of the fifteenth century and twenty-two of the seventeenth century. Periodicals include bound volumes in eight languages. The collection also includes his correspondence as editor of the *American Journal of Diseases of Children* since 1923, and as secretary of the American Academy of Pediatrics.

Chicago

Dr. Huggins Awarded Fenwick Prize.—Dr. Charles Huggins, professor of urology at the University of Chicago School of Medicine, has been awarded the Fenwick Prize, a gold medal, by the Société Internationale D'Urologie for work on the endocrine control of cancer of the prostate.

Research in Biochemistry.—The University of Illinois College of Medicine has received $7,000 from Mead Johnson and Company, Evansville, Ind., to support a two year fellowship in research in biochemistry in the department of pediatrics, under the supervision of Dr. Henry G. Poncher, head of the department.

Postgraduate Courses.—The Chicago Medical Society will present two postgraduate courses this fall, at Thorne Hall, Northwestern University. The course in hematology and neurology will be given September 13-18 and another in cardiovascular and respiratory diseases September 20-25. The faculty includes leading teachers from throughout the United States who will present an intensive review of special fields for both the general practitioner and the specialist. Each course is limited to 100 and carries a fee of $50.

IOWA

State Medical Election.—At the annual meeting of the Iowa State Medical Society, Dr. James E. Reeder, Sioux City, was installed as president; Dr. Nathaniel G. Alcock, Iowa City, was made president-elect; Dr. Allan B. Phillips, Des Moines, secretary, and Dr. N. Boyd Anderson, Des Moines, treasurer.

Society News.—The Linn County Medical Society meeting, Cedar Rapids, will hear Dr. George W. Corner, Baltimore, speak on "Twins, Triplets, Quads and Quints" September 1. At the meeting on October 15, Dr. Max M. Strumia, Bryn Mawr Hospital, Bryn Mawr, Pa., will address the society on "Intravenous Protein Feeding."

MAINE

Dedicate Unit at Jackson Laboratory.—Dedication ceremonies were held August 7 marking the first completed unit of reconstruction of the Roscoe B. Jackson Memorial Laboratory at Bar Harbor. These buildings, a group for summer students, were made possible by a gift from the Ladies Auxiliary to the Veterans of Foreign Wars. Speakers included James R. Angell, LL.D., president of Jackson Laboratory, and Dr. James B. Murphy, head of cancer research at Rockefeller Institute, New York, a trustee of the laboratory.

MICHIGAN

Dr. Heustis Appointed State Health Commissioner.—Dr. Albert E. Heustis Jr., Coldwater, was appointed state commissioner of health August 3. He has been director of the county health department and the Community Health Center of Branch County since 1945 and was previously director of the Monroe County Health Department. Dr. Heustis was graduated from the University of Michigan Medical School, Ann Arbor, in 1936 and from 1937 to 1940 served as intern, assistant resident, resident and teaching assistant in the department of surgery of the university. In 1942 he received a Master of Public Health degree from Johns Hopkins University. He is a trustee of the Michigan Hospital Association and a member of its legislative committee and is vice president and a member of the board of directors of the Southwestern Michigan Hospital Council, a trustee and member of the state hospital relations committee of the Michigan Hospital Service and a nonresident lecturer in public health administration for the University of Michigan School of Public Health.

NEW YORK

State Department Positions Available.—The State of New York Department of Civil Service, Albany, will hold examinations October 2 for an associate cancer radiologist, a senior psychiatrist and a biochemist. These are open to residents of any state in the country On that date examinations will also be held for a junior pharmacist and a senior laboratory technician (tuberculosis), which will be limited to legal residents of the state.

Fellow in Industrial Psychiatry.—The first industrial psychiatry fellow in the School of Industrial and Labor Relations at Cornell University, Ithaca, will be Dr Graham C Taylor, Montreal, Canada. The fellowship is part of the school's new program to train psychiatrists for the industrial and labor relations field. Dr. Taylor will begin a two year program at the school in September, dividing his time during the fellowship between studies and research on the campus and first hand investigations in industrial plants.

New York City

Dr. Brooks to Head Physiology Department.—Chandler McC. Brooks, Ph.D., associate professor of physiology at the Johns Hopkins University School of Medicine, Baltimore, since 1933, has been appointed professor of physiology and pharmacology and director of that department at the Long Island College of Medicine. Dr. Brooks has recently returned from New Zealand and Australia, where he spent two years as a Guggenheim Fellow.

Emotional Problems of Disabled.—A grant of $73,500 from the Commonwealth Fund will be used at New York University-Bellevue Medical Center for a three year research project on the emotional problems of the physically disabled while undergoing rehabilitation training. Dr. Morris Grayson will direct the research. The project will evaluate the motivating factors in physical rehabilitation and the emotional factors that interfere with it and study what psychiatry can contribute in preparing persons for rehabilitation.

Civil Service Appointments Available.—The City of New York Civil Service Commission is opening applications September 15-30 for six positions:

Assistant medical examiner—appointment at $5,150
Neuropathologist, Grade 4—appointment at $4,650
Pathologist—appointment at $4,650
Director of Bureau of Tuberculosis, Grade 4—appointment at $7,500
Director, division of psychiatry—appointment at $7,500
Alienist (psychiatry), Grade 4—appointments as follows:
  1 at $6,650; 12 at $6,150; 1 at $5,790; 2 at $5,650; 3 at $5,150; 3 at $4,150

Applications may not be made by mail.

Diagnostic and Periodic Health Examination Service.—The department of health has announced plans for its new diagnostic and periodic health examination service. The diagnostic service will be available only to patients referred by private physicians, and the patient will be sent back to the referring physician for treatment. It is an extension of the existing consultation service of the department into fields involving chronic and noninfectious diseases, nutrition and mental hygiene and aims to meet the needs of families of ordinary means. The first "pilot clinic" will be opened in the department's Lower West Side Health Center at 303 Ninth Avenue, Manhattan. About 300 patients a month will be accepted for diagnostic consultation. Any physician in New York can make the service available to his patient by filling out a blank available at the department of health. A complete report will be sent to the referring physician. The service will be for ambulatory patients only.

The periodic health examination service will be provided for persons sent by their physicians and persons from groups selected for such study by the department of health. It will involve apparently well persons. The department is interested in making such examinations as a means of getting information that will indicate the true health status of persons at various age levels and as a means of emphasizing that such periodic examinations are advisable for adults. When disability is found, the patient will be advised to go to his private physician or to seek the service of a hospital clinic.

NORTH CAROLINA

Booklet on Blood Bank.—A 16 page booklet, "Management of a Blood Bank," which describes methods used at North Carolina Baptist Hospital and Bowman Gray School of Medicine of Wake Forest College, Winston-Salem, is being distributed to hospitals throughout the state. The booklet was prepared for the North Carolina Maternal Welfare Committee by Dr. Mary I. Griffith, instructor in obstetrics and gynecology. Procedures and technics of setting up and operating a blood bank are fully discussed and illustrated.

OREGON

Annual State Medical Meeting.—The Oregon State Medical Society will hold its annual session at the Medford Hotel, Medford, September 15-18, under the presidency of Dr. James C. Hayes of that city. The guest speakers will be four clinicians from the University of Michigan Medical School, Ann Arbor:

Henry K. Ransom, Treatment of Diseases of the Breast.
Norman F. Miller, Diagnosis and Treatment of Carcinoma of the Cervix
Cyrus C. Sturgis, Medical Management of Thyroid Disease
Arthur C. Curtis, Cutaneous Manifestations of Systemic Disease

Roundtable luncheon discussions are scheduled for each day, the subjects being prevention and treatment of thromboembolism, Wednesday; hypertension, Thursday; management of bleeding of late pregnancy, Friday, and occupational and contact dermatoses, Saturday. The speaker at the annual banquet will be G. Herbert Smith, LL.D., president, Willamette University, Salem, on "Education in a Democracy."

PENNSYLVANIA

Personal.—Dr. Samuel L. Grossman, Harrisburg, was elected president of the Pennsylvania Society for Crippled Children and Adults at its silver anniversary meeting in May.——Dr. Russell S. Anderson, Erie, has been elected to the board of directors of the Pennsylvania Tuberculosis Society as the official representative of the Medical Society of the State of Pennsylvania.

Organize Trudeau Society.—The Pennsylvania Trudeau Society has recently been organized as the medical section of the Pennsylvania Tuberculosis Society with Dr. Frank A. Craig, director of clinics at the Henry Phipps Institute, Philadelphia, president, and Dr. Leon H. Collins Jr., Philadelphia, secretary-treasurer. The organization meeting was held at the close of the annual meeting and conference of the Pennsylvania Tuberculosis Society.

Philadelphia

Course in Diagnosis and Treatment of Cancer.—Temple University School of Medicine and Hospital is offering alumni and general practitioners a course in the early diagnosis and treatment of cancer, September 13-17. Drs. Elmer Hess, Erie, and George T. Pack, New York, will speak at the only evening program, September 15. There is no registration fee. Applications should be made to Dean William N. Parkinson at the university.

Research at Temple.—Temple University School of Medicine and Hospital has received the following grants from the U. S. Public Health Service: (1) $20,152 for continuation of the research project "Electrokymography of the Heart and Blood Vessels" by Drs. W. Edward Chamberlain, George C. Henny and Bert R. Boone; (2) $8,000 to finance one year's work by Dr. Machteld E. Sano on "The Lability of the Lymphomata"; (3) $4,000 to finance one year's work by Dr. Mona Spiegel-Adolf on problems of "Ultra-Spectrographic Studies of Nucleic Acids in Tumors"; (4) $10,000 to Dr. Valy Menkin on the problem of "The Relation of Cellular Injury to the Development of Neoplasia," also the "Chemotherapy of Experimental Leukemia," and (5) $18,500 on the problem "Physical and Physiological Studies of the Heart and Circulation." The National Advisory Health Council has also awarded a grant of $6,000 in support of research by Dr. Robert H. High on "Study of Effect of Streptomycin in Combination With Other Drugs in the Treatment of Tuberculosis in Infants and Children." From the Bureau of Medicine and Surgery, U. S. Navy, $6,180 to Robert H. Peckham, Ph.D., has been made for "The Experimental Determination of Neutrality in Sunglasses." Two awards from pharmaceutical companies include a grant of $27,555 from Smith, Kline & French for research in pharmacology and $1,200 from John Wyeth, Inc., for medical research.

Pittsburgh

Society Election.—At a meeting of the Pittsburgh Obstetrical and Gynecological Society Dr. James Hodgkiss was elected president and Dr. Clarence H. Ingram Jr., secretary.

Appointments to Psychiatric Institute.—Recently announced appointments to the staff of Western State Psychiatric Institute and Clinic include: Dr. Frederick L. Weniger, director of the outpatient division of the institute, and Dr. Ralph N. Zabarenko, associate research psychiatrist. In a reorganization of the division of neurophysiology in the department of research Robert H. Patton, Ph.D., has been named research neurophysiologist. Newly appointed resident fellows included Roger W. Russell, Ph.D., and Harry W. Braun, Ph.D., respectively associate professor of psychology and lecturer in psychology at the University of Pittsburgh. Dr. Robert A. Clark, clinical director of the institute, is on a year's leave of absence to attend the International Congress on Mental Health in London in August and to study under C. G. Jung at the Institute of Analytical Psychology in Switzerland.

TEXAS

Personal.—Dr. Webb Walker was honored at a testimonial dinner on his retirement as chairman of the board of the City-County Hospital, Fort Worth, June 3. Dr. Walker, who joined the board in 1918, is succeeded by Dr. Demetrius M. Rumph.

Appoint Professor of Biochemistry.—Wendell H. Griffith, Ph.D., professor of biochemistry, St. Louis University School of Medicine, St. Louis, has accepted appointment as professor of biochemistry and nutrition and chairman of the department at the University of Texas Medical Branch, Galveston. Dr. Griffith has been associated with the biochemistry department of St. Louis University School of Medicine since 1923. He served during World War II as colonel in the Sanitary Corps and was responsible for nutrition surveys among American troops.

WASHINGTON

Admnistrative Assistant Needed.—The state department of health is receiving applications for an administrative assistant in the Hospital Planning and Development Section. The position is in Seattle and carries a salary range of $295 to $360 per month. Duties will be to assist the head of the section in planning and supervising the collection, tabulation and analysis of data pertinent to hospital construction needs. Applications and information are available from the state department of health, Seattle.

Society News. — The Pacific Northwest Obstetrical and Gynecological Association was formed at a meeting in Spokane by representatives from the Northwestern district of the United States and Canada, including Alaska. Membership is limited to members of the profession who are specialists certified by either the American or the Canadian Board of Obstetrics and Gynecology. Officers elected were: Howard C. Stearns, Portland, Ore., president; E. Murray Blair, Vancouver, British Columbia, president-elect, and Richard D. Reekie, Spokane, secretary-treasurer.

WEST VIRGINIA

Center Changes Name. —The name of the Kanawha Valley Medical Center in South Charleston has been changed to "West Virginia Medical Center." The change was approved by the House of Delegates of the West Virginia State Medical Association. The type of service rendered will in no way be affected. The institution is being operated for the exclusive treatment and control of syphilis and gonorrhea for all of the fifty-five counties in West Virginia. Patients are referred to the center by private physicians and officials of local health departments.

Outbreak of Tracheobronchitis.—The recent outbreak of respiratory disease in Tucker County is considered to have been tracheobronchitis, according to a semifinal report submitted to the state department of health by the U. S. Public Health Service. A total of 27 cases was reported from the area, the first in February and the last one in June. The disease, which has been sporadic, has affected only infants and children. The 4 deaths occurred in children under 2 years of age. According to Dr. Newman H. Dyer, state health commissioner, a similar type of disease has been found during the past year in Mineral County, and in Cumberland, Md.

WISCONSIN

Form Public Health Council. — The Wisconsin Public Health Council, aimed at improving public health by disseminating public health information and encouraging the development of adequate public health services throughout the state, was formed May 12. It comprises forty-five citizens under the temporary chairmanship of William J. Deegan, city manager of Superior. The new organization will not duplicate existing agencies, but will be representative of all organized groups and individuals whose interest involve health.

Anesthesiologists to Meet.—The Wisconsin Society of Anesthesiologists invites all doctors in Wisconsin to a series of four panel discussions on the autonomic nervous system as it is concerned in all surgical operations, September 19, in the auditorium of the Service Memorial Institute, Madison. The last twenty or thirty minutes of each hour will be used for questions from the floor. There is an advance registration fee of $1; residents in hospitals are invited without fee but are requested to make their reservations in advance. Information may be obtained from Dr. William Kreul, 811 Main Street, Racine.

WYOMING

Annual State Medical Meeting.—The Wyoming State Medical Society will hold its annual meeting September 1-3 at the Connor Hotel and the Wyoming Union Building, Laramie, under the presidency of Dr. Emory W. DeKay, Laramie. Guest speakers include:

John B. Grow, Denver, Exploratory Thoracotomy in Obscure Intrathoracic Disease.
B. Marden Black, Rochester, Minn., Status of Goitrogenic Drugs, Radioiodine and Surgery in Treatment of Diseases of the Thyroid Gland.
Ward Darley, Denver, Diagnosis of the Active Rheumatic State.
Harold S. Morgan, Lincoln, Neb., Management of Breech Presentation.
Constantine F. Kemper, Denver, Changing Concepts About Diabetes Mellitus.
George F. Lull, Chicago, Secretary and General Manager, American Medical Association.
Ralph M. Stuck, Denver, Management of Head Injuries in General Practice.
Robert Ward, New York, Poliomyelitis—Distribution of Virus and Pathways of Spread.
Benedict J. Duffy, Rochester, N. Y., subject to be announced.

The Woman's Auxiliary will meet September 1-2 in conjunction with the state association.

PUERTO RICO

Number of Puerto Rico Doctors.—According to the Medical Association of Puerto Rico, a total of 190 Puerto Rican medical students have received free scholarships from the Insular Government to study in the United States and Mexico. Thirty-four of these students will receive their doctor's certificates this year. There are 752 doctors in active service in Puerto Rico, of whom 61 are foreigners who are practicing with special licenses. The new doctors will serve in government institutions for a period of five years.

Hospital Construction Program.—The U. S. Public Health Service has approved the hospital construction program, thus permitting Puerto Rico to take advantage of federal funds for this purpose. In addition to the construction to be undertaken with federal and insular funds, the Government of Puerto Rico has already under construction eighteen municipal hospitals and thirty public health units. While the Island has the necessary funds to take care of the hospital construction program during the next two years, operating expenses of the program will prevent Puerto Rico from taking advantage of federal appropriations for the program after the first two years of the five years contemplated in the construction already planned. It is estimated that for each bed provided the insular government will have to expend $1,500 annually for maintenance.

GENERAL

Reclaiming Used Gauze Sponges.—The Hospital Bureau of Standards and Supplies, Inc., has issued a report on "Reclaiming Used Gauze Sponges" by Dewey H. Palmer, research director. The seven page mimeographed report may be obtained from the Research Department, Hospital Bureau of Standards and Supplies, Inc., 247 Park Avenue, New York 17, for 50 cents.

Tuberculosis Death Rate at New Low.—According to the National Tuberculosis Association, the tuberculosis death rate in the United States reached a new low of 33.2 per 100,000 population in 1947. The increase in the number of new cases was credited to improved case-finding methods. The number of reported deaths from tuberculosis dropped below 50,000 for the first time with 47,636 deaths as compared with 50,911 in 1946.

Medical Illustrators' Meeting.—The Association of Medical illustrators will hold its third annual meeting in Chicago, September 27-30, at the Sheraton Hotel. The association, founded in 1945 in Chicago, is under the presidency of Mr. Willard C. Shepard, medical art director at W. B. Saunders Company. The first Brödel Memorial Lecture will be given at the annual banquet September 27 by Barry J. Anson, Ph.D., Northwestern University Medical School, Chicago.

Tuberculosis Sanatorium Directory.—The National Tuberculosis Association has issued its 1948 "Tuberculosis Sanatorium Directory" listing 830 institutions with 120,496 beds for patients with tuberculosis. Seventeen institutions with 2,940 beds are located in Alaska, Hawaii and Puerto Rico. Exclusive of beds in state mental and penal institutions, the total number available in 1947 was 99,179, an increase of 1,453 beds since 1942, when the last directory was published.

Association of Nurse Anesthetists.—The fifteenth annual meeting of the American Association of Nurse Anesthetists will be held in Atlantic City, N. J., September 20-23, with three general sessions emphasizing the clinical, theoretical and professional aspects of anesthesia. Speakers will include: Dr. Albert Faulconer, Rochester, Minn.; Dr. Alfred Blalock and

Miss Olive Berger, Johns Hopkins Hospital, Baltimore; Dr. Esther M. Greisheimer, Temple University School of Medicine, Philadelphia; Dr. Vincent P. J. Collins, Doctors' Hospital, New York, and Emanuel Hayt, attorney-at-law, New York.

Mortality Rate Remains Low.—According to the Institute of Life Insurance, New York, the health record among U. S. life insurance policyholders during the first half of this year has continued at or near the record low of last year. During the first six months tuberculosis has continued to decline to 40 per cent under that of ten years ago. The 1948 improvement in all major childhood diseases except measles over last year's record low brought the rate to a level of about one fifth that of ten years ago. The influenza death rate is well under last year's and about one third of that ten years ago. Only deaths due to heart disease and cancer show increases.

Human Genetics Society of America.—This recent organization aims to bring into closer contact investigators interested in human genetics and to deal with related problems. The membership at present is about 250, drawn from the fields of anthropology, child development, genetics, immunology, medicine, psychology, sociology, statistics and others. The president for 1948-1949 is Hermann J. Muller, D.Sc., Bloomington, Ind. The society will hold its first meeting at Washington, D. C., September 11-13. Information relative to membership may be obtained from the secretary, Herluf H. Strandskov, D.Sc., Department of Zoology, University of Chicago, Chicago 37.

Instructors of Medical Record Library Science.—The American Association of Medical Record Librarians will sponsor an institute for instructors in medical record library science October 13-16, in Los Angeles, if enough instructors are interested. Applicants other than present instructors must meet the following requirements: age, 23 to 45 years; college or university degree; graduation from an approved school for medical record librarians, and at least two years' medical record library experience. Tuition for others attending will be $25. Information may be secured from Mrs. Edna K. Huffman, American Association of Medical Record Librarians, 22 East Division Street, Chicago.

Society Elections.—The New England Dermatological Society has elected Dr. Francis M. Thurmon, Boston, president; Dr. G. Marshall Crawford, Brookline, Mass., secretary, and Dr. Mildred L. Ryan, Brockton, Mass., treasurer.——At the meeting of the American Society for the Study of Arteriosclerosis, Dr. William B. Kountz, St. Louis, was elected president; Dr. Otakar J. Pollak, Quincy, Mass., secretary-treasurer. The next annual scientific meeting will be held October 31-November 1 at the Hotel Knickerbocker, Chicago.——At the recent meeting of the Central Surgical Association, Dr. Henry K. Ransom, Ann Arbor, Mich., was installed as president; Dr. J. Dewey Bisgard, associate professor of surgery at the University of Nebraska College of Medicine, Omaha, president-elect; Dr. Walter G. Maddock, Chicago, secretary, and Dr. James T. Priestley, Rochester, Minn., treasurer.

Roentgen Ray Society Meeting.—The American Roentgen Ray Society will hold its annual meeting at the Palmer House, Chicago, September 14-17, under the presidency of Dr. Lawrence Reynolds, Detroit. The program includes a roundtable discussion of Bronchogenic Carcinoma and symposiums on the Diagnostic, Roentgenographic and Surgical Aspects of Congenital Heart Disease; Diagnosis and Treatment of Diseases of the Chest and Group Consultation; the Intensification of the Roentgenoscopic Screen Present Day Roentgenoscopes and Their Deficiencies and Advances in Radiology. Other papers will be presented by speakers from throughout the country. The Caldwell Lecture will be presented by Dr. Byrl R. Kirklin, Rochester, Minn., on "Graduate Education in Roentgenology." The annual banquet will be held Thursday evening.

Changes in Board of Obstetrics and Gynecology.—The American Board of Obstetrics and Gynecology in annual session in Washington, D. C., May 16-22, elected Dr. Walter T. Dannreuther, New York, president, and Dr. Paul Titus, Pittsburgh, secretary-treasurer. Dr. Daniel G. Morton, San Francisco, was appointed to fill the unexpired term of Dr. Edward A. Schumann, Philadelphia, representing the American Gynecological Society, and Dr. Robert A. Kimbrough Jr., Philadelphia, the unexpired term of Dr. Ludwig A. Emge, San Francisco, representing the Section on Obstetrics and Gynecology of the American Medical Association. The board at the examination meeting certified 231 candidates. A number of changes in board requirements and regulations were made. New bulletins are now available for distribution on application and give details of all new regulations. These relate both to candidates and to hospitals conducting residency services for training. Foremost are the following: 1. The ruling that applicants must receive adequate training in both obstetrics and gynecology has been defined as meaning a minimum of six months, full time, in the branch of either obstetrics or gynecology relegated to a minor role in a candidate's training and preference for practice. 2. Acceptable preceptorship training is defined. 3. The present regulation requiring at least six months of practice in the specialty following the completion of an acceptable training period has now been extended, effective Dec. 31, 1949, to a requirement of two years post-training practice limited to the specialty. 4. Specific requirements for approval of hospital services for residency training are outlined. 5. Effective immediately, there will be no further temporary approvals of hospital services for residency training. All future approvals will be based entirely on inspection following application. It is expected also that certain resurveys will result in withdrawal of present residency approval from institutions where the educational and training standards are not being maintained. The next scheduled examination (Part I), written examination and review of case histories, for all candidates will be held in various cities of the United States and Canada on Friday, Feb 4, 1949. Applications may be made until Nov. 1, 1948. Application forms and bulletins are sent on request made to American Board of Obstetrics and Gynecology, Inc., 1015 Highland Building, Pittsburgh 6, Pa.

FOREIGN

Great Britain

Arthritis Aid Units.—The Canadian Press reports that Lord Horder, physician to the King and a leader of the war on arthritic diseases, has planned a squad of two hundred mobile physical therapy units to carry the latest treatment to every small town in England. There will be two fully trained physical therapists to each truck. Trained operators of the electrical equipment have been traveling in Britain for more than a year in twelve trucks.

Germany

Max Planck Society.—*The New York Times* reports that a new German scientific association called the Max Planck Society for Advancement of Science has been founded with Dr. Otto Hahn, Nobel Prize winner who first split the uranium atom, as head. The society will take the place of the Kaiser Wilhelm Institute, which once sponsored more than fifty research associations but was dissolved by the Allied Control Council in 1946. Complete freedom of research has been guaranteed, subject only to the council's prohibition of military research. Ten other Nobel Prize winners have joined Dr. Hahn in founding the new society.

CORRECTION

"Demerol."—In the abstract "'Demerol' and Opium Alkaloids in Biliary Spasm," in THE JOURNAL, July 24, 1948, page 1163, the last sentence should read "as the pain is due to biliary obstruction other than spasm relief will not be afforded by the nitrites; morphine or meperidine may be given for the relief of this type of pain." In the abstract the last part of this sentence had been deleted.

Marriages

HARRY RANDOLPH HULL NICHOLAS III, Flanders, N. J., to DR. MARGARET HASLET DOYLE of Brooklyn in Bay Ridge, N. Y., June 3.

RALPH ULYATE WHIPPLE, West Englewood, N. J., to Miss Joan Dorothy Hopkins of Maidenhead, England, May 8.

ROBERT BIRCHALL, Port Washington, N. Y., to Miss Anne Lancaster Tinsley of Spartanburg, S. C., May 24.

KAM-FAI CHAN to Miss Lau-Chun Kwan, both of Hong Kong, China, in New York in June.

ROBERT EMMET GORDON, Brooklyn, to Miss Jeanne Frances Dillon in Newburgh, N. Y., June 5.

GRAHAM ALEXANDER VANCE, Bristol, Tenn., to Miss Martha Gordon Miller of Chicago, June 5.

ALEXANDER J. MOZZER, New York, to Miss Ann Kuczynski of Northampton, Mass., June 19.

ALFRED JOSEPH COLE, Baltimore, to Miss Roselda Katz of Shaker Heights, Ohio, June 22.

RICHARD P. KEATING, New York, to Miss Barbara Nogas of East Hampton, Conn., June 12.

WILLIAM PRICE GIVEN, New York, to DR. PHYLLIS CASSEDY, in Newburgh, N. Y., May 8.

Deaths

Samuel McClintock Hamill ⊕ died at his home in Philadelphia, May 3, aged 83, of cardiac failure. Dr. Hamill was born in Oak Hall, Pa., Nov. 3, 1864. He was graduated from Princeton and then was graduated from the University of Pennsylvania Department of Medicine in 1888. In 1892 he joined the faculty of the University of Pennsylvania and from 1901 to 1919 was professor of diseases of children at the old Philadelphia Polyclinic and College for Graduates in Medicine and at the University of Pennsylvania Graduate School of Medicine, 1919-1920. A specialist certified by the American Board of Pediatrics, Dr. Hamill was past president of the American Pediatric Society, the American Child Health Association of which he had been for many years member of the executive committee, the American Association for the Study and Prevention of Infant Mortality and of the Philadelphia Child Health Society. He was a founder and past president of the American Academy of Pediatrics and of the Philadelphia Pediatric Society, which presented him in 1933 with a medal for notable service and achievement in the field of child health. He was the first chairman of the section on pediatrics of the Medical Society of the State of Pennsylvania and in 1911 was chairman of the Section on Diseases of Children of the American Medical Association. In 1919 he was chosen one of three delegates from the United States to the International Conference on Public Health and Child Welfare in France. Dr. Hamill served in 1930 as chairman of Section I on Medical Service of President Hoover's White House Conference on Child Health and Protection. From 1933 to 1939 he was chairman of the Pennsylvania State Emergency Child Health Committee, and in 1936 the Medical Society of the State of Pennsylvania presented him with an illuminated manuscript in recognition of this service. The Philadelphia County Medical Society in 1939 conferred on Dr. Hamill the Strittmatter Award. He was a fellow of the College of Physicians of Philadelphia, a member of the Pathological Society of Philadelphia, Neurological Society of Philadelphia, Mental Hygiene Committee of Public Charities Association of Pennsylvania and the mayor's milk commission of Philadelphia. During 1917 and 1918 he was a member of the general medical board of the Council of National Defense, chairman of its National Child Welfare Committee, director of child welfare for the state of Pennsylvania and chief of the division of child hygiene of the Pennsylvania State Department of Health. Dr. Hamill was on the staff of St. Christopher's Hospital for Children, chief of pediatric departments of the Howard Hospital, Philadelphia Polyclinic Hospital and the Presbyterian Hospital, where he was consulting pediatrician. He was a member of the board of managers of the Babies' Hospital and board of directors of the Philadelphia Child Guidance Clinic, a former chairman of the health department, Council of Social Agencies, Welfare Federation of Philadelphia, vice president of Philadelphia Social Service Exchange and member of the Charities and Welfare Committee of the Philadelphia Chamber of Commerce. At one time Dr. Hamill was a member of the board of trustees of the Lawrenceville School and the Oak Lane Country Day School. In 1928 and 1929 he was president of the Society of the Alumni of the Medical Department of the University of Pennsylvania. In 1940 he was awarded the Doctor of Science degree from the University of Pennsylvania, and in 1941 the alumni award of merit.

Millard Knowlton ⊕ Hartford, Conn.; born in Colfax County, Neb., Feb. 18, 1875; Medical College of Indiana, Indianapolis, 1905; at one time participated in the tuberculosis control program for the New Jersey State Department of Health; received public health degree from Harvard-Massachusetts Institute of Technology School of Public Health; served with the U. S. Public Health Service Reserve; during World War I assigned to venereal disease control work in this country; other assignments included work with the Kansas State Board of Health and duty in Montana; did venereal disease control work in North Carolina from 1919 to 1921 and from there was detailed to Veterans Bureau until 1923; on April 1, 1923 came to the Connecticut State Department of Health as director of the bureau of preventable diseases, where he remained until his retirement in 1946; fellow of the American Public Health Association and a past president of the Connecticut Branch of the Society of American Bacteriologists; member of the Connecticut Public Health Association, American Society for the Advancement of Science and the American Epidemiological Society; died in St. Francis Hospital May 4, aged 73, of coronary thrombosis.

Marshall Peterson Gordon Jr., ⊕ Richmond, Va.; born in Richmond, Oct. 26, 1904; University of Virginia Department of Medicine, Charlottesville, 1927; interned at the Johns Hopkins Hospital in Baltimore, where he served a residency; interned at the University of Virginia Hospital in University; assistant professor of urology at the Medical College of Virginia and urologist for the hospital division of the college; specialist certified by the American Board of Urology; member of the American Urological Association and the Richmond Academy of Medicine; served in the medical corps of the U. S. Naval Reserve during World War II; on the staffs of the Retreat for the Sick, Stuart Circle, St. Elizabeth's and Sheltering Arms hospitals; died May 10, aged 43, of coronary thrombosis.

Grant Orante Favorite ⊕ Haddonfield, N. J.; born in Ortucchio, Italy, June 20, 1903; Hahnemann Medical College and Hospital of Philadelphia, 1927; associate in bacteriology and immunology at Jefferson Medical College in Philadelphia; served as professor of bacteriology at his alma mater; member of the American Society of Clinical Pathologists; fellow of the American College of Physicians; during World War II a major in the medical corps of the Army of the United States from September to November 1942; on the staff of the West Jersey Hospital in Camden, where the Grant O. Favorite Research Laboratory was established and named in his honor; died May 4, aged 44, of heart disease.

James Madison Batchelor, Waveland, Miss.; Medical Department of Tulane University of Louisiana, New Orleans, 1895; at one time associate professor of clinical surgery at his alma mater; for many years practiced in New Orleans, where he was formerly president and professor of surgery at the Loyola Post-Graduate School of Medicine, superintendent of public health and chairman of the board of health for the parish of Orleans and city of New Orleans, consultant for the city board of health and on the staffs of Presbyterian and Charity hospitals; died in Baptist Hospital, New Orleans, May 17, aged 77, of complications following injuries received in a fall.

Wesley Emmet Gatewood ⊕ Portland, Ore.; born in Stockport, Ohio, March 7, 1891; Rush Medical College, Chicago, 1915; associate clinical professor of medicine at the University of Oregon Medical School; specialist certified by the American Board of Internal Medicine; member of the North Pacific Society of Internal Medicine and the Portland Academy of Medicine; formerly on the faculty of the State University of Iowa College of Medicine in Iowa City; served overseas during World War I; on the staffs of the Portland Sanitarium and Hospital, Emanuel Hospital and the Multnomah Hospital; died May 23, aged 57, of coronary thrombosis.

Heywood Hill Hopkins ⊕ Rochester, N. Y.; born in Thomasville, Ga., Sept. 13, 1896; Harvard Medical School, Boston, 1922; instructor in orthopedic surgery at the University of Rochester School of Medicine and Dentistry; specialist certified by the American Board of Orthopaedic Surgery, Inc.; member of the Rochester Academy of Medicine and the Rochester Pathological Society; affiliated with the Veterans Administration Hospital and the Memorial Hospital in Bath, the Genesee Hospital, Monroe County Hospital and the Strong Memorial Hospital; died May 13, aged 51, in an airplane accident.

John Falconer Sinclair ⊕ Philadelphia; born in Orange, N. J., Feb. 18, 1871; University of Pennsylvania Department of Medicine, Philadelphia, 1897; emeritus professor of pediatrics at the Medico-Chirurgical College, Graduate School of Medicine, University of Pennsylvania; specialist certified by the American Board of Pediatrics, Inc.; past president of the Philadelphia Pediatric Society; member of the American Academy of Pediatrics; one of the founders and formerly medical director of Babies' Hospital; served on the staff of Presbyterian Hospital; died May 11, aged 77, of arteriosclerosis and rheumatic heart disease.

William Schroeder Jr., Northport, N. Y.; born in Brooklyn, June 4, 1879; Long Island College Hospital, Brooklyn, 1901; member of the American Medical Association; fellow of the American College of Surgeons; served overseas during World War I and later with the Fourteenth Infantry of the Brooklyn National Guard; formerly chairman of the sanitation commission of New York City and commissioner of the department of hospitals; affiliated with Cumberland, Coney Island, Prospect Heights and Caledonian hospitals, Brooklyn; died May 1, aged 68, of coronary sclerosis.

Henry Hervey Abegg, Dougherty, Iowa; State University of Iowa College of Medicine, Iowa City, 1898; member of the American Medical Association; died May 11, aged 74, of heart disease and cirrhosis of the liver.

Nathan Addelson, Brookline, Mass.; Tufts College Medical School, Boston, 1908; died April 30, aged 66, of cerebral thrombosis.

Carlton Stewart Allen, Los Angeles; University of Southern California School of Medicine, Los Angeles, 1909; member of the American Medical Association; served during World Wars I and II; for many years assistant medical director of the state department of unemployment; died May 4, aged 63, of myocarditis.

Charles Edgar Allen Jr., ⊕ Baton Rouge, La.; Louisiana State University Medical Center, New Orleans, 1936; medical director of the Louisiana division of the Esso Standard Oil Company; member of the staffs of Baton Rouge General Hospital and Our Lady of the Lake Sanitarium, where he died May 17, aged 43, of polycystic kidney disease.

Thomas Jefferson Andrews, Faitbury, Neb.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1882; died in Lincoln April 10, aged 96, of cerebral hemorrhage.

John William Harmon Beach, Arlington, Ohio; Fort Wayne College of Medicine, 1898; member of the American Medical Association; served during World War I; died May 13, aged 75, of carcinoma.

Harry Hallowell Bowles ⊕ Summit, N. J.; University College of Medicine, Richmond, Va., 1909; fellow of the American College of Surgeons; served during World War I; for many years chief of staff of Overlook Hospital, where he resigned in 1946 and became consulting surgeon; died May 29, aged 63, of coronary thrombosis.

Thomas Patrick Boyle, Newark, N. J.; Baltimore Medical College, 1902; served during World War I; formerly on the staffs of St. James' Hospital and Babies' Hospital, Coit Memorial; died May 17, aged 71, of coronary occlusion.

Edward Pliny Brewer, Miami, Fla.; Dartmouth Medical School, Hanover, N. H., 1879; died May 10, aged 88, of senility.

John Cabot, Weehawken, N. J.; College of Physicians and Surgeons, medical department of Columbia College, New York, 1886; at one time affiliated with the Roosevelt Hospital and Vanderbilt Clinic in New York; died May 12, aged 93, of chronic nephritis and arteriosclerosis.

Alexander Carlyle Cameron, Erie, Pa.; University of Pittsburgh School of Medicine, 1911; died May 9, aged 63, of rupture of right subclavian artery.

Alfred Cornwell, Bridgeton, N. J.; Jefferson Medical College of Philadelphia, 1894; died May 27, aged 77, of gastric carcinoma.

Ersom Mills Cunningham ⊕ Cassopolis, Mich.; Medical College of Indiana, Indianapolis, 1892; past president of the Cass County Medical Society; for many years on the staff of the Lee Memorial Hospital, Dowagiac, Mich., where he died May 13, aged 80, of cerebral hemorrhage.

Nelson Lloyd Deming, Daytona Beach, Fla.; Columbia University College of Physicians and Surgeons, New York, 1893; died May 1, aged 80, of coronary thrombosis.

William Devitt ⊕ Allenwood, Pa.; Medico-Chirurgical College of Philadelphia, 1902; member and past president of the American College of Chest Physicians; fellow of the American College of Physicians; specialist certified by the American Board of Internal Medicine; served as president of the Pennsylvania Tuberculosis Society and the Federation of American Sanatoria; medical director of Devitt's Camp, which he founded; died May 23, aged 73, of coronary occlusion.

Fred Strayer Diefendorf, Angola, N. Y.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1898; member of the American Medical Association; for many years health officer of the town of Evans and the village of Angola; died in the Gowanda State Homeopathic Hospital, Helmuth, May 19, aged 75, of arteriosclerosis and prostatic hypertrophy.

Otto G. Draper, Chicago; Missouri Medical College, St. Louis, 1898; member of the American Medical Association; on the staff of Henrotin Hospital; died in Round Lake, Ill., May 21, aged 79, of cerebral arteriosclerosis.

Maurice Joseph Drell ⊕ Seattle; University of Illinois College of Medicine, Chicago, 1940; specialist certified by the American Board of Ophthalmology; interned at the Cook County Hospital in Chicago; he served a residency in ophthalmology at the University of Chicago Clinics; affiliated with Harborview and Virginia Mason hospitals; died May 20, aged 30, of cardiovascular renal disease.

Frederick Warren Ellis ⊕ Newton Centre, Mass.; Harvard Medical School, Boston, 1881; an Affiliate Fellow of the American Medical Association; last original member of the American Physiological Society; member of the American Association for the Advancement of Science; died April 30, aged 91, of pulmonary tuberculosis.

Le Roy William Flora, Anchorage, Alaska; University of Minnesota Medical School, Minneapolis, 1940; certified by the National Board of Medical Examiners; member of the American Medical Association; served as a member of the Alaska Board of Medical Examiners; killed in a plane crash June 17, aged 40.

Dwight Bailey Fuller, Philadelphia; University of Pennsylvania Department of Medicine, Philadelphia, 1892; also a dentist; formerly member of the Common Council; member of the Association of Military Surgeons of the United States; served on the staffs of the Polyclinic and Howard hospitals; died in Philadelphia General Hospital May 16, aged 84, of intracapsular fracture of left femur, as the result of a fall, arteriosclerosis and bronchopneumonia.

James Albert Fulton, Kansas City, Kan.; College of Physicians and Surgeons, Medical Department Kansas City University, Kansas City, 1903; member of the American Medical Association; served during World War I; past president of the board of education; formerly chief medical officer of the Kansas National Guard; one of the organizers and for many years president of the Brotherhood State Bank; for forty-four years anesthetist at Bethany Hospital, where he died May 9, aged 68, of coronary disease.

James Burton Gillis, Portland, Ore.; University of Oregon Medical School, Portland, 1911; died May 13, aged 72, of carcinoma of the bladder.

Horace Gledhill ⊕ Brooklyn; Jefferson Medical College of Philadelphia, 1923; on the staffs of the Methodist, Norwegian and Victory Memorial hospitals; died May 2, aged 49, of coronary disease.

John Calvin Greenfield, Avon, S. D.; Bennett Medical College, Chicago, 1898; member of the American Medical Association; died in Sioux City April 21, aged 72, of a malignant tumor.

Peter George Grimm ⊕ Spirit Lake, Iowa; Rush Medical College, Chicago, 1893; served as president of the Dickinson County Medical Society; for many years county coroner and surgeon for the Chicago, Milwaukee and St. Paul Railroad; died in Spirit Lake Hospital May 14, aged 76, of heart disease.

Harry M. Harman, Frenchtown, N. J.; Jefferson Medical College of Philadelphia, 1887; also a registered pharmacist; served as mayor of Frenchtown and as member and president of the school board; on the staff of the Easton (Pa.) Hospital; died in Mount Pleasant, May 25, aged 83, of carcinoma of the prostate.

Ernest C. Harris, Sylvester, Ga.; Atlanta College of Physicians and Surgeons, 1913; member of the American Medical Association; served as examining physician for the Selective Service for many years; died in Piedmont Hospital, Atlanta, April 26, aged 64, of cerebral hemorrhage.

William Norris Hubbard ⊕ New York; College of Physicians and Surgeons, medical department of Columbia College, New York, 1886; for many years affiliated with the Manhattan Eye, Ear, Nose and Throat Hospital; died April 21, aged 87.

Buel Latcher, Yonkers, N. Y.; Albany (N. Y.) Medical College, 1897; city health department district physician for many years; on the staff of St. John's Riverside Hospital; died in the Aurelia Osborn Fox Memorial Hospital, Oneonta, May 21, aged 73, of cirrhosis of the liver.

John Leedom ⊕ Philadelphia; University of Pennsylvania Department of Medicine, Philadelphia, 1905; associate professor of surgery at the Temple University School of Medicine; died April 24, aged 66, of acute cardiac failure.

Robert Matthew Levin, Boston; University of Vermont College of Medicine, Burlington, 1938; associated with Massachusetts Memorial Hospitals; served overseas during World War II; died in South Paris, Maine, April 30, aged 34, of coronary occlusion.

Harriet Maynard Lewis, Portland, Me.; Woman's Medical College of Pennsylvania, Philadelphia, 1884; died in the Mercy Hospital April 16, aged 91, of cerebral hemorrhage.

Louis Pard L'Homme, Lowell, Mass.; College of Physicians and Surgeons, Boston, 1919; died April 12, aged 54, of cirrhosis of the liver.

Maurice Rosenthal Lohman ⊕ Fort Wayne, Ind.; University of Michigan Medical School, Ann Arbor, 1915; past president of the Indiana Tuberculosis Association; for many years president of the Allen County Tuberculosis Association; past president of the Fort Wayne and Allen County Medical Society; member of the board of directors of Irene Byron Sanatorium; died in St. Joseph Hospital April 29, aged 58, of bilateral pyelonephritis and hypertrophied prostate.

Clark Russell William Magill ⊕ Chicago; University of Illinois College of Medicine, Chicago, 1924; served during World War II; on the staff of Garfield Park Community Hospital and St. Anne's Hospital, where he died May 30, aged 50, of injuries received in an automobile accident.

Horatio Richmond Marsh, Long Beach, Wash.; New York Homeopathic Medical College and Hospital, New York, 1897; member of the American Medical Association; for many years a medical missionary in Alaska; member of the fire department; died in Warrenton, Ore., May 6, aged 74, of arteriosclerosis.

Dorothy Ruth Mattingly ⊕ Baton Rouge, La.; Louisiana State University School of Medicine, New Orleans, 1939; specialist certified by the American Board of Radiology, Inc.; served a residency at the Charity Hospital in New Orleans; on the staffs of Our Lady of the Lake Sanitarium and the Baton Rouge Hospital; died in Tucson, Ariz., April 23, aged 33, of hemorrhage from aneurysm of left vertebral artery.

George Wilson Terry Mills, Brooklyn; University and Bellevue Hospital Medical College, New York, 1902; member of the American Medical Association and the American Psychiatric Association; specialist certified by the American Board of Psychiatry and Neurology, Inc.; formerly medical superintendent of the Brooklyn State Hospital and the Creedmoor State Hospital in Queens Village, N. Y.; died in the Methodist Hospital May 8, aged 67, of gastric hemorrhage.

Donald Martin Norton ⊕ Medford, Wis.; Marquette University School of Medicine, Milwaukee, 1926; for many years secretary of the Price-Taylor Counties Medical Society; formerly fellow in medicine at the Mayo Foundation in Rochester, Minn.; city health officer; affiliated with the Medford Clinic-Hospital; died May 5, aged 50, of carcinoma of the liver.

Walter Orthner ⊕ Huntingdon, Pa.; Temple University School of Medicine, Philadelphia, 1930; formerly secretary of the Huntingdon County Medical Society; president of the board of health; on the staff of the J. C. Blair Memorial Hospital; died April 21, aged 47, of sarcoma.

Marcus Ostro ⊕ Baltimore; University of Maryland School of Medicine, Baltimore, 1914; member of the Radiological Society of North America, Inc., and the American College of Radiology; specialist certified by the American Board of Radiology; on the staffs of the Johns Hopkins University Hospital and Sinai Hospital, where he died May 12, aged 58, of subarachnoid hemorrhage.

Boris Rapoport ⊕ New York; Tufts College Medical School, Boston, 1914; specialist certified by the American Board of Anesthesiologists; member of the American Society of Anesthesiologists; formerly on the faculty of his alma mater; for many years chief anesthetist at the Beth Israel Hospital in Boston; since 1937 head of the department of anesthesia at the Hospital for Joint Diseases, where he died May 4, aged 59, of coronary thrombosis.

Jacob Reiner ⊕ Elizabeth, N. J.; University and Bellevue Hospital Medical College, New York, 1908; past president of the Union County Medical Society; fellow of the American College of Surgeons; served during World War I; during World War II examining physician for a local draft board; city school physician; on the staff of Elizabeth General Hospital; died May 9, aged 60, of coronary thrombosis.

Francis Llewellyn Rogers, Long Beach, Calif.; State University of Iowa College of Medicine, Iowa City, 1891; member of the Long Beach Eye, Ear, Nose and Throat Society and of the Los Angeles Society of Ophthalmology and Otolaryngology; one of the founders of Seaside Memorial Hospital; died April 30, aged 83, of uremia.

Charles Compton Roosa, Buffalo; University of Buffalo School of Medicine, 1899; died in Buffalo General Hospital May 9, aged 91, of carcinoma of the bladder and mitral stenosis.

William Asbury Rourk, Myrtle Beach, S. C.; Jefferson Medical College of Philadelphia, 1924; member of the American Medical Association; served as a member of the city council and city school board; died May 18, aged 50, of coronary thrombosis.

Charles Joseph Rowan ⊕ Laguna Beach, Calif.; Rush Medical College, Chicago, 1898; served on the faculties of his alma mater, State University of Iowa College of Medicine in Iowa City and the University of Southern California School of Medicine in Los Angeles; member of the American Surgical Association and Western Surgical Association; fellow of the American College of Surgeons; died in Los Angeles May 7, aged 73, of pulmonary embolism and chronic nephritis.

Robert Montfort Schley ⊕ Buffalo; Hahnemann Medical College and Hospital of Philadelphia, 1902; member of the American Psychiatric Association; specialist certified by the American Board of Psychiatry and Neurology, Inc.; on the staffs of the Millard Fillmore and Edward J. Meyer Memorial hospitals; psychiatrist to Erie County Probation Department; died May 5, aged 70, of myocarditis with congestive failure.

William Jefferson Smith, Williamsburg, Ky.; University of Louisville Medical Department, 1909; died April 21, aged 65, of cerebral hemorrhage and pneumonia.

William Henry Speer ⊕ Wilmington, Del.; University of Pennsylvania School of Medicine, Philadelphia, 1910; served as president and secretary of the Medical Society of Delaware; fellow of the American College of Surgeons; formerly mayor of Wilmington; served during World War I; formerly chief of staff of St. Francis Hospital; member and formerly chief of staff of Delaware Hospital, where he died May 3, aged 60, of pneumonia.

George Martin Spilka, Pittsburgh; Jefferson Medical College of Philadelphia, 1938; affiliated with St. John's Hospital; died April 4, aged 38, of pneumonia.

Carroll Mortimer St. Clair, Cambridge, Md.; Howard University College of Medicine, Washington, D. C., 1928; died in the Cambridge-Maryland Hospital April 1, aged 49, of coronary thrombosis.

George Thomas Watkins Jr. ⊕ Durham, N. C.; Jefferson Medical College of Philadelphia, 1915; affiliated with the Watts Hospital; died May 11, aged 56, of coronary thrombosis.

Kenneth Johnson Wilson ⊕ Oklahoma City, Okla.; University of Oklahoma School of Medicine, Oklahoma City, 1916; died April 23, aged 57, of carcinoma of the lungs.

DIED WHILE IN MILITARY SERVICE

Arthur Katz, Baltimore; Johns Hopkins University School of Medicine, Baltimore, 1942; interned at Sinai Hospital; began active duty in the medical corps, Army of the United States, in August 1943; in July 1944 went overseas with 102d General Hospital to England; promoted to captain in January 1945; killed in a vehicle accident near Bensheim, Germany, Feb. 27, 1946, aged 28, in line of duty as medical officer of 7th Army Ordnance Technical School at Heidenheim, Germany.

Fred Coleman Mackler, New York; University of Virginia Department of Medicine, Charlottesville, 1944; interned at the Harlem Hospital, where he served a residency; began active duty as a first lieutenant in the medical corps, Army of the United States, May 1, 1946; promoted to captain; died in Walter Reed General Hospital, Washington, D. C., July 30, 1947, aged 26, of glioma.

Paul James Ritchie ⊕ Lieutenant Commander M.C., U. S. Navy, San Diego, Calif.; University of Southern California School of Medicine, Los Angeles, 1938; interned at California Hospital in Los Angeles; appointed a lieutenant (jg) in the medical corps of the U. S. Navy on May 16, 1938; died June 23, 1944, aged 32, when the plane in which he was a passenger crashed into the Pacific Ocean.

Benjamin Stoller, Brooklyn; New York Homeopathic Medical College and Flower Hospital, New York, 1922; began active duty as a captain in the medical corps, Army of the United States, in November 1942; died April 17, 1946, aged 50, of hypertension and coronary sclerosis.

Richard Provost Wilson ⊕ *Lieutenant Commander* M.C., U. S. Navy, Minneapolis; Syracuse University College of Medicine, 1936; interned at the Brooklyn Hospital; appointed a lieutenant (jg) in the medical corps of the U. S. Navy on May 8, 1939; died Feb. 26, 1944, aged 31, of injuries received when the plane in which he was a passenger crashed near the Naval Air Station, Olathe, Kan.

Thurston William Laraway, Hood River, Ore.; University of Oregon Medical School, Portland, 1924; formerly health officer of the village of Elk River; major, medical corps, Army of the United States; died in the Regional Hospital, Camp Joseph T. Robinson, Ark., July 9, 1945, aged 49, of pneumonitis.

Treatment of Tuberculous Laryngitis by Tyrothricin

At one of the last meetings of the Society of the Paris Hospitals, J. Fouquet presented about 50 cases of tuberculous laryngitis treated with two to three daily injections of streptomycin. He noted an improvement in the functional disorders within two to three days, the cicatrization of the anatomic lesions within two to three weeks. Infiltrating forms are slower in responding. He has discarded local streptomycin treatment by powder or aerosols. At the same meeting, P. Bourgeois and V. Dupont presented their results of local treatment of tuberculous laryngitis by tyrothricin. They gave four daily applications of a suspension of this antibiotic, the concentration being 0.5 or 1 mg. per cubic centimeter. The authors have noted the disappearance of pain and the removal of dysphagia in 7 cases out of 7 (100 per cent); improvement of edema in 3, improvement of ulcerations in 2, inappreciable effect on vegetations and no modifications of infiltrations. The authors emphasize the advantages offered by this treatment: (1) perfect tolerance; it is superior, in this respect, to streptomycin; (2) the treatment can be given without hospitalization; (3) it is less expensive than streptomycin. The authors are of the opinion that the association or the alternate use of tyrothricin and streptomycin could procure more complete anatomic recoveries.

New Method of Melanophore Diagnosis of Pregnancy

L. Servantie and F. Moretti have just perfected a melanophore method for the diagnosis of pregnancy. This test differs from the previous methods by the following characteristics: 1. Complete hypophysectomy of the frog (Rana esculenta) under binocular lens. 2. Verification of the test animal: microscopic examination of the interdigital membrane of the posterior leg; any animal not presenting a complete contraction of melanophores is to be rejected. Although decoloration be complete after five to six hours, the authors use the animal only on the day following hypophysectomy. 3. Establishment of a melanophoric index giving an objective and quantitative measure of the melanophoric potency; a reading is made under microscope half an hour and an hour after injection of a quantity of urine equal to 0.1 per cent of its weight in the dorsal lymphatic sac. 4. Elimination of the cause of error initiated by the agonic dilation of melanophores. The reading is valid if animals survive for two hours. 5. Perfection of a simple process for the concentration of the melanophorodilator hormone in the urines, when there is a doubt. The authors have performed more than 200 tests. This test has shown itself of an absolute specificity, security and fidelity, verified from the beginning to the end of the pregnancy. The result of this test has been constantly negative in the normal man and woman, in Addison's disease and pigmentary cirrhosis. The authors have found no paradoxic reaction when varying from 5 to 8 the p_H of injected urine. Beside its specificity, this process offers the advantages of rapidity, one hour in urgency cases, and also the use of an animal easily kept in the laboratory without any special precaution.

Attempts at Reanimation After Acute Anoxemia

Professor L. Binet, Dean of the Paris Faculty of Medicine, and M. Strumza have been successful in reviving animals after cessation of the respiratory action and of the beating of the heart by means of transfusing oxygenated blood through the carotid artery. The authors have made progress in this field. Through pulmonary oxygenation and transdiaphragmatic massage of the heart, they have revived asphyxiated dogs ten, fifteen and twenty minutes after stopping of the heart, when the reanimation process was begun from two to seven minutes and forty seconds after the heart had stopped. The technic is as follows: After laparotomy, the hand is slipped above the liver and thus its back is resting on the heart; forty to sixty times a minute pressure is put on the heart, in order to maintain an arterial tension of at least 60 to 100 mm. of mercury. At the same time, an effective artificial respiration is kept up, the trachea being connected with a container of pure oxygen. The subject regularly survives when reanimation is undertaken within two minutes and thirty seconds after the heart stops; survival is frequent after three minutes and thirty seconds and possible after seven minutes and thirty seconds. When the heart has resumed beating (ten to twenty minutes of massage being necessary), recurrence of respiration always follows. Associating oxygenotherapy with massage of the heart insures a necessary minimum of oxygenation to the tissues and, especially, to nervous centers and the heart. Certain medicaments, ineffective as long as the tissues are anoxemic, regain their efficiency after artificial oxygenation; in this way, an injection of epinephrine in a heart stopped for three minutes will induce hypertension only after three minutes and fifteen seconds of massage and oxygenation. The authors emphasize that manual transdiaphragmatic compressions of the heart, associated with inhalation of pure oxygen, surpass, as a method of reanimation in asphyxia, all other procedures.

TURKEY

Ankara, July 25, 1948.

Trachoma Campaign

Trachoma was endemic in the Eastern and Southeastern provinces of Turkey before the first World War and it became epidemic as the result of troop movements through Iraq, Transjordan, Syria and Palestine. In 1927 a survey sponsored by the Ministry of Health revealed that in some localities the rate of incidence was 10 to 30 per cent and in others 70 to 80 per cent. At the second national medical congress in Ankara in 1927 trachoma was a lively subject for discussion and a campaign against it was recommended. The trachoma control zone then included the provinces of Gaziantep, Urfa, Marash, Diyarbakir, Mardin, Malatya, Adana and Mersin, with the city of Gaziantep as central control station. The campaign started in 1930 with a small staff of specialists with six 100 bed hospitals and six dispensaries at their disposal; 78,620 persons, of whom more than half were in need of treatment, were examined. In 1934 there were ten 132 bed hospitals and 21 dispensaries; 87,815 persons were examined, of whom 47,105, or 53 per cent, were found infected and 1.6 per cent were blind from trachoma; treatment (eye drops) was given 2,059,786 times. In 1937 the eight provinces had units in thirty-six villages. In 1938 there were thirteen hospitals with 160 beds, and twenty-one dispensaries (patients requiring an operation remained in the hospital two to three weeks). Minor operations, curative and preventive treatment, as well as instruction concerning the prevention of trachoma, were given at the dispensaries. All operations, treatment and medicaments are free and paid for from the government budget. During 1938 of the 171,563 persons examined 111,954, or 65 per cent, were infected and 2.6 were blind from trachoma; treatment was given 4,742,661 times. In 1945 it became necessary to divide the trachoma area into two zones with control centers at Adana and Diyarbakir. In 1947 there were sixteen hospitals with 225 beds, thirty-four village units and sixty-nine dispensaries; 96,309 persons were examined; 45,311, or 55 per cent, found infected and 1.5 blind; treatment was given 6,527,455 times. At present there are thirty-eight hospitals with 225 beds, thirty-eight dispensaries and one hundred and seven village units.

Trachoma control work is at present carried on in fifteen provinces with a population of 3,623,986. In the trachoma campaign zone 1,910,632 persons, or 47.5 per cent, are trachomatous. At present there are 49 specialists, 127 sanitary inspectors, 3 visiting nurses, 16 hospital nurses and a clerical staff of 23 employed in the trachoma campaign. In the trachoma regions from 1 to 3 per cent are in the infectious stage and from 3 to 5 per cent are blind from chronic trachoma. Seriously ill persons are admitted to the hospitals; others receive treatment at the dispensaries. The personnel of the village units is responsible for finding trachoma-infected persons in the rural communities, for providing treatment or seeing to it that they get what they require at a dispensary or hospital.

Trachoma-infected children are sent to special schools. The extermination of flies and their breeding places is given special attention, also the examination of trades people handling food or drinks. To procure an efficient personnel, courses for the training of sanitary inspectors and nurses are held in the trachoma zones. Health education is an important part of the campaign: A million illustrated pamphlets and posters have been distributed; radio talks are given; special talks are given and motion pictures shown in schools and talks and motion pictures on trachoma prevention to mothers.

The zone directors make frequent inspection tours and once a month send a detailed report to the ministry of health.

Among the new plans for 1949 conducive to the eradication of trachoma are a demand for more allocation, more means of motor transportation, more medical and other personnel, more special schools for trachoma-infected children, letters of commendation and money rewards for especially good work, new laws and regulations and securing the cooperation of the United Nation's World Health Organization. The campaign is organized and directed by the trachoma division of the ministry of health. The ministry appoints physicians, nurses, sanitary inspectors and clerical personnel, who are all of the civil service.

ITALY

FLORENCE, July 2, 1948.

Cancer of the Prostate

This important problem was reviewed at the recent Congress of the Italian Society of Surgery. The first speaker, Prof. E. Mingazzini, reported on the diagnosis of carcinoma of the prostate and on indications for surgical intervention; he emphasized the importance of early diagnosis and the relation between hypertrophy and cancer of the prostate. The difficulties of early diagnosis are numerous, but elements of right judgment may be drawn from accurate evaluation of subjective urinary symptoms. Disturbances of micturition, which may be associated with hypertrophy as well as with cancer, have some different characteristics: the incidence of hematuria is greater in cancer (24 per cent against 8 per cent), while urinary retention presents lower percentages in cancer than in hypertrophy. Sudden irradiating pain before and after micturition, and occurring simultaneously with various other disturbances, seems characteristic of cancer of the prostate.

Diagnostic data may be revealed by objective examination, during which four possibilities may be present: (1) little or localized changes in the lobes of the prostate, which are smooth, not indurated and not painful; under these conditions a diagnosis is impossible; (2) increase in volume of the lobes of the prostate with more or less smooth appearance but in the presence of hard nodules; the diagnosis is difficult and dubious; (3) increased volume of the lobes of the prostate in the presence of small or median nodules which are disseminated and extremely hard; the diagnosis is certain; (4) the lobes of the prostate present a woodlike, hard consistence, without definite borders; under such circumstances the diagnosis becomes simple.

The changes which must be taken into consideration are as follows: the shape (deformation may occur in 83 per cent of the cases), the surface (which will be changed in 65.5 per cent), the consistence (increased in 92.4 per cent), pain (almost always present on palpation in the cancerous zone), and the border (uncertain in 50 per cent of the cases). The many tests which may be carried out to evaluate the clinical picture, such as examination of the urine, renal function tests and tests for eosinophilia, are of little value. Cystometric studies may be of doubtful value. Among the roentgenographic studies only vesiculography may furnish reliable data.

The chemical tests, such as Abderhalden's reaction, and those of Fuchs and Freund and Kaminer, may offer doubtful data; that applies also to studies of phosphatase; in cancer without metastasis, the phosphatase is normal or little increased; in cancer with metastasis the increase of phosphatase is considerable.

The disadvantage of biopsy is that it is difficult if puncture instruments are used.

Professor Mingazzini said that profound disagreement divides various authors on the question whether or not cancer of the prostate may be operable. Statistics show that the number of patients with operable cancer is limited. Young operated on 24 patients during a period of twenty-one years. Crevy operated on 3 of 275 patients whom he had seen in the course of seven years. Berringer carried out surgical intervention in 16 of 235 cases. In cases in which the tumor is associated with hypertrophy there is more ample indication for intervention.

In cases of circumscribed or localized tumors, removal is the method of choice, and preferably by the perineal route. All other types of treatment, such as endoscopic resection, ligature of the excretory ducts of the testicles, castration and the application of radium or roentgen rays were of little help.

The second part of the subject, hormone therapy of the cancer of the prostate, was reported on by Dr. Musiani. The estrogenic substances most frequently used are synthetic products: diethylstilbestrol, hexestrol and dienestrol. The last one is more effective than the two others and is particularly suitable for the treatment of recurrences. The estrus-producing compounds may be administered orally, subcutaneously or, better, intramuscularly.

The initial doses vary from 10 to 20 mg. per day, by mouth, until improvement is obtained; then maintenance treatment should be carried out with 0.25 mg. per day, continued without interruption. Immediate success may be obtained in 51 per cent of the cases, but the treatment should be considered only as a palliative, since recurrences are observed in a great number of cases over a period varying from eight months to two years. The improvement which may be obtained consists in the rapid disappearance of pain from metastasis, in the reduction of the primary tumor and improvement of the general condition.

Treatment with hormones brings about a degeneration of the cancerous epithelium not only in the primary tumor but also in the metastasis in the lymph nodes; changes in metastasis of bones can be demonstrated on roentgenographic examination in only 9 per cent of cases.

Adenocarcinoma seems to be the type of tumor which may be benefited best by hormone therapy. The majority of authors prefer combined treatment (orchiectomy associated with administration of estrus-producing compounds), because by this procedure the main source of the androgens may be removed.

Correspondence

THE TERMINOLOGY OF SOMATIC CHANGES ACCOMPANYING EMOTIONAL STATES

To the Editor:—A number of considerations have convinced us of the need for a specific term to denote certain bodily changes resulting from emotional disturbance. We have already proposed (The Journal **132:**1053, 1946) the term "emotogenic" to designate alterations in gastric function which may occur in association with affective states unrelated to the taking or conscious thought of food. In the present communication we will discuss the origin of this term and some of its broader uses and implications.

Our attention was first drawn to this problem when, in going over the literature on the effect of emotions on gastric secretion, we became aware that there is no way of knowing, when a paper bears the term "psychic effects" in its title, whether it deals with "appetite" secretion or emotionally conditioned secretion.

The stimulation of gastric secretion by emotional states acting over the vagal pathway is often termed a type of "psychic" secretion. Had not this term already been applied to another definite physiologic phenomenon there would be no objection to such usage. However, the term "psychic" secretion has become firmly rooted in physiologic literature as a designation for the secretion of gastric juice by the vagal reflex mechanism in which the sight or thought of food (in the presence of appetite) is the stimulus. This is the original sense in which the term was used by Pavlov.

After it had been demonstrated that gastric secretion in response to sham feeding could occur in the absence of the cortex, it was proposed that the term "cephalic" phase of gastric secretion be used to designate secretion which occurred in response to stimuli acting in the region of the head. The latter term includes, then, the psychic and appetite secretion of Pavlov as well as any secretion which may occur when stimuli (food) act in the region of the head but in the absence of cortical participation. Secretion occurring in association with emotional states cannot be considered a type of cephalic secretion, since the latter is a phase of digestive secretion, whereas an emotional secretion is not. The conventional classification of gastric secretion may then be presented in slightly revised form as follows:

I. Interdigestive period:
    1. Interdigestive or "continuous" phase (*occurring in the absence of any known stimulus*)
    2. Emotional phase
II. Digestive period:
    1. Cephalic phase
    2. Gastric phase
    3. Intestinal phase

In our psychosomatic studies on patients with peptic ulcer, we find that we can sometimes spend all morning exploring various aspects of the patient's history or his present environmental stresses without getting a "rise" out of his stomach, until finally he begins looking at his watch and trying to twist his head around to see how the kymographic tracing is progressing. If a period of gastric activity ensues, we are not certain whether it is "psychic" in that the conversation in itself, or the subject matter, has made him resentful, or whether it is "psychic" in the pavlovian sense due to the proximity of the lunch hour.

In view of these problems, we were led to adopt the term "emotogenic" to designate changes in motility and secretion accompanying affective states. Two further examples will suffice to illustrate the need for, and the use of, this term.

A decrease in gastric secretion associated with distaste or disgust for food which has an unpleasant odor or appearance is a "psychic" inhibition, whereas a decreased secretion associated with sorrow, or fear, or any emotion not related to food, is an "emotogenic" inhibition.

The second example involves a more finely drawn distinction. A period of elevated motility and secretion while a patient is sleeping is always of interest to us in view of the possible association with a dream. We always awaken the patient during or immediately after such a period to ask him whether he was dreaming, and if so, what the content of the dream was. Occasionally the dream concerns food and the question arises whether the gastric activity is psychic, i. e., associated with the thought of food, or whether it is emotogenic, i. e., associated with an unconscious emotional conflict symbolized by food. Obviously, a dream of eating may be experienced by a person who has no emotional conflict relating to or symbolized by food or eating. A person who does not get enough to eat is constantly preoccupied during his waking moments with thoughts of food; if he dreams of food, it is most likely a carry-over of his conscious thoughts. In this case, an increase in gastric activity during the dream would most reasonably be considered "psychic."

But, in working with ulcer patients we are dealing with the possibility raised by Alexander's theory; namely, that a dream of eating may be a symbol of the unconscious wish to be fed. Such a dream seemingly has no relation to the conscious thought of, or desire for, food because the ulcer patients under our observation are getting three meals and three interval feedings. Yet the conscious factor may enter in; ulcer patients are usually on a restricted diet and often express a longing for a juicy steak (fried in onions, as a rule). It may be that the nature of the food dreamed about might offer a clue as to whether an associated increase in gastric activity is psychic or emotogenic.

O. S., a 39 year old salesman with a ten year history of duodenal ulcer, had been boarded out with relatives at the age of 7, following the death of his mother. Throughout his childhood and adolescence he was tolerated, not loved. Of those years he has many bitter recollections, few pleasant ones.

During a motility and secretion study, while the patient was asleep a brief period of gastric activity occurred. On being awakened, the patient related a dream of a man in a white uniform tending a fruit stand at a busy intersection. The "busy intersection" is a well chosen symbol of our laboratory, and the significance of the "man in white" dispensing food seems obvious. Since fruit is not what a hungry man generally pictures when he thinks of eating, and since this patient professed no particular yearning for fruit, it may be that the food in this dream symbolizes the emotional conflict situation postulated by Alexander. If so, and if the observed gastric activity was indeed related to the dream, one might interpret this as an emotogenic hyperactivity of the stomach.

We have given due consideration to the applicability of the existing term "psychogenic" to the phenomena described, but there are two objections: First, such nomenclature is not specific for the physiologic processes concerned. That is, "psyche" refers to the mind or mental processes; whence arises the second objection; namely, that the word "psychogenic" carries the erroneous and unwelcome implication that there is a derangement of the mind or that the symptoms are "in the mind," i. e., are "imaginary."

By contrast the term herein proposed recognizes and gives credence to a symptom or physiologic aberration and places its origin squarely in the sphere of the emotions. Thus, we speak of emotogenic vomiting, emotogenic diarrhea, pain due to emotogenic dyssynergia of the colon, and so on. With this terminology, the inaccurate and clinically distasteful combining forms "psycho-" and "neuro-" not only are circumvented but are replaced by a precise nomenclature.

MEDICOLEGAL ABSTRACTS

Evidence: Party's Right to Continuance if Expert Witness Cannot Be Present.—The plaintiff sued for damages for personal injuries following a collision between an automobile operated by the plaintiff and a station wagon operated by the defendant. From a judgment for the plaintiff, the defendant appealed to the Supreme Court of Appeals of Virginia.

The defendant's main assignment of error on appeal concerned the action of the trial court in refusing to grant a continuance on the defendant's showing that his only expert witness would not be able to be present at the trial. The plaintiff, who before the accident was strong, healthy and brilliant, sustained substantial and permanent injuries, among which was a serious impairment of mental powers. The defendant's attorney employed a brain specialist to examine the plaintiff and later testify for the defendant as an expert witness. Furthermore, because of the extremely technical nature of brain injury cases, the defendant's attorney also planned to use the expert as a consultant during the trial to advise him in the cross examination of the plaintiff's experts. One week before the day set for the trial, this expert advised the defendant's attorney that he had made arrangements to leave Norfolk in five days for a vacation in Mexico City and would not return for about six weeks. The attorney said that he would try to obtain a continuance but that, failing to obtain it, he would not be willing to excuse him because he needed his help too much. In other words, if the court would not grant a continuance, the attorney said that he would have a subpoena issued to assure the expert's presence. The trial judge refused to grant a continuance and, in addition, advised the expert that he would not take disciplinary action against him if he failed to obey the subpoena.

When a litigant seeks the opinion and aid of an expert in a trial, said the Supreme Court, the relationship between the parties is different from that of an ordinary witness summoned to testify to some pertinent fact known to him. In the former case the duty of the witness to attend the trial and give testimony, or otherwise aid the litigants, is created by contract. In the latter case the duty of a witness to attend the trial and testify is a duty created by law and arises out of necessity in the administration of justice. A witness of either class, however, when properly served with a subpoena must attend the trial or be subject to punishment for contempt of court.

When the defendant's expert notified the attorney of his desire to be absent from Norfolk on the day of the trial, continued the Supreme Court, the attorney immediately moved the court for a continuance on the ground of such expected absence. This motion was overruled. Two days later the expert requested the court to excuse him from attending the trial, which request was granted over the objection of the defendant's attorney. The trial court held in effect that it was more important for the expert to take his vacation than it was for the defendant to have the benefit of his expert testimony and aid at the trial, an issue, said the Supreme Court, which should have been left to be settled between the attorney and the expert.

The plaintiff was demanding that defendant pay her $75,000. She was prepared to back this demand with the force of the testimony of seven physicians, each of whom later emphasized some particular phase of her disability. The defendant's attorney did not know at the time he made the motion just what the seven physicians would state. He did know that they were witnesses for the plaintiff and that they would testify on every phase of her distressing condition. He was not a brain specialist. He needed the aid of a medical expert to help him analyze the testimony of the physicians introduced by the plaintiff in order to cross examine them intelligently. This aid the expert could have given, in addition to giving the jury the benefit of an expert opinion on the plaintiff's condition stated from the defendant's point of view. In these circumstances, said the Supreme Court, the defendant's attorney could not state with any degree of accuracy the probable testimony of his expert. Indeed, the expert himself did not know what his opinion would be, as it depended on the result of his examination of the plaintiff and the history of her case as it would be outlined by the plaintiff's witnesses. His opinion might have been in accord with the views of the plaintiff's physicians, but he might have stated it in such language as would have tended to reduce the amount of compensation to which the jury believed the plaintiff was entitled. Regardless of the value or the weight which the jury might have given to his testimony, the defendant was entitled to have the jury weigh the opinion of the well known and reliable medical expert employed by him. While the evidence does not disclose that the defendant's attorney made an express promise to pay the expert a specific sum for his opinion and aid at the trial, the statements of the defendant's attorney and the letters of the expert to him clearly reveal that the attorney engaged him soon after the action was instituted, consulted him from time to time and had every reason to expect the expert's aid and cooperation throughout the trial.

There is not a scintilla of evidence which tends to support the conclusion that the motion for continuance was made for the purpose of delaying the trial. The decision of the trial court in granting the expert's request to be excused was prejudicial to the defendant in that it deprived him of the opportunity to present to the jury the testimony of the only expert witness the defendant had engaged and who, he had every reason to believe, would cooperate and aid him in the trial. The plaintiff, said the court, is entitled to substantial compensation, but in ascertaining the amount it was and is the duty of the trial court to give the defendant a fair opportunity to present the views of a medical expert employed by him. This was not done. The Supreme Court therefore reversed the judgment for the plaintiff and remanded the case for further hearing. *Bradley v. Poole, 47 S. E. (2d) 341 (Va., 1948).*

Legitimacy of Child Produced by Artificial Insemination.—The plaintiff wife filed a motion to determine the defendant's right to visit the minor child of the two parties. The motion was heard in the Supreme Court, Special Term, New York County, Part I.

The court assumed, in the light of the record and the concessions made by the defendant, that the plaintiff was artificially inseminated with the defendant's consent and that the child is not of the blood of the defendant. The court then held that the child had been potentially adopted or semiadopted by the defendant. In any event, said the court, in so far as this defendant is concerned, and with particular reference to visitation, he is entitled to the same rights as those acquired by a foster parent who has formally adopted a child, if not the same rights as those to which a natural parent in the circumstances would be entitled. Furthermore, said the court, assuming again that the plaintiff was artificially inseminated with the consent of the defendant, this child is not an illegitimate child. Indeed, logically and realistically the situation is no different from that pertaining in the case of a child born out of wedlock who is by law made legitimate on the marriage of the interested parties. The court said that it would not pass on the legal consequences in so far as property rights are concerned in a case of this character, nor would the court express an opinion on the propriety of procreation by the medium of artificial insemination. The latter problem particularly, said the court, is in the field of sociology, morality and religion. Accordingly, the defendant was granted the right to visit the minor child at certain specified times.—*Strnad v. Strnad, 78 N. Y. S. (2d) 390 (N. Y., 1948).*

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1938 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied with stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Supradiaphragmatic Splanchnicectomy in Hypertension.—Isberg and Peet report on 384 patients with arterial hypertension, treated surgically by bilateral supradiaphragmatic splanchnicectomy and lower dorsal sympathetic ganglionectomy. Sixty per cent of patients with hypertensive heart disease were still living five to twelve years after splanchnicectomy. Of the hypertensive patients with normal hearts 93 per cent were still living five to twelve years after operation. Patients whose electrocardiograms show inverted T waves in leads I and II, or definite left axis deviation and abnormal T waves, have a 50 per cent chance for prolonged survival following splanchnicectomy. Of the patients still alive, 41 per cent of those with abnormal preoperative electrocardiograms recently showed significant improvement in their tracings five years or more after operation, and 44 per cent of those with preoperative cardiac enlargement recently showed significant decrease in heart size. Practically all patients who have shown improvement in electrocardiogram or decrease in heart size have maintained a significant reduction in blood pressure. Fifty per cent of hypertensive patients in whom an enlarged heart was demonstrated have not survived five to twelve years. Splanchnic resection is of no avail in cases of cardiac enlargement with a variation greater than 50 per cent of predicted normal for frontal area or transverse diameter. The patient with paroxysmal nocturnal dyspnea has little chance for benefit from splanchnic resection. Anginal seizures were frequently relieved after splanchnicectomy. Of patients with gallop rhythm prior to operation, almost a fourth have survived five years or more. The hypertensive patient in congestive heart failure which requires digitalization preparatory to splanchnicectomy stands 1 chance in 3 for prolonged survival following operation. Eight out of 11 hypertensive patients who had a coronary occlusion and were subsequently treated with splanchnic resection were still living five to nine years after operation. Comparing the spontaneous evolution of the electrocardiogram in hypertension in a control group with the evolution in hypertensive patients who had abnormal electrocardiagram prior to splanchnic resection, it may be said that splanchnicectomy has beneficially influenced the destiny of the hypertensive patients with abnormal electrocardiograms who have been fortunate enough to have lived five years and longer after operation.

Hereditary Disturbance in Cholesterol Metabolism and Atherosclerosis.—Boas and his associates say that the comparatively frequent appearance in the same person of arcus senilis, coronary atherosclerosis and elevated serum cholesterol suggests that they are more than coincidental. The authors studied 122 patients with symptoms of coronary artery disease and electrocardiographic evidence of myocardial damage, in whom symptoms appeared under 50 years of age. Each was examined for the presence of arcus senilis, xanthelasma and xanthoma. One or more serum cholesterol determinations were made by the method of Bloor. It was possible to investigate the families, chiefly siblings, of 50 of these patients. The average serum cholesterol for the 71 patients who exhibited hypercholesterolemia was 365 mg. per hundred cubic centimeters, and the average among the remaining 51 patients was 250 mg. per hundred cubic centimeters. Arcus senilis was exhibited by 22, xanthelasma by 12 and xanthomatosis by 3 of the group. The great majority with these stigmas had elevated serum cholesterol levels. Hypercholesterolemia (serum cholesterol of 300 mg. per hundred cubic centimeters or more) was found in all or most of the siblings of one third of fifty families of patients with coronary atherosclerosis. In 9 more families, one half of the siblings exhibited hypercholesterolemia. This study lends support to previous clinical investigations and indicates that a disturbance in cholesterol metabolism is probably concerned in the genesis of some instances of coronary atherosclerosis. It also suggests that altered cholesterol metabolism may be the common denominator in most patients with coronary artery disease and arcus senilis, or coronary artery disease and xanthelasma. One of the hereditary factors responsible for arteriosclerotic heart disease may reside in abnormal cholesterol metabolism.

Sclerosis of Coronary Artery and Sudden Death.—The observations reported by Rabson and Helperin were made in the course of necropsies in 2,030 cases in which death was unexpected in that the victims were apparently healthy at the time of death, and sudden because death took place usually within twenty-four hours after the onset of symptoms. The designation "natural death" indicates that death resulted exclusively from disease unassociated with external violence or poisoning. In 45 per cent of these cases death was attributed to diseases of heart and aorta. Of these, two thirds (30.4 per cent of the 2,030 cases) were caused by coronary arteriosclerosis. This percentage of coronary artery disease in the cardiac and aortic group corresponds almost exactly with that reported from Berlin, Germany, over an eight year period. Sudden death from coronary artery sclerosis occurred most frequently in white men. The three decades between 44 and 74 years contributed one and one-half times their percentage share of the population, but sudden death from this disease began to appear in the third decade. Death took place under no specific circumstances. In almost three fourths of the hearts, coronary artery sclerosis, and not fresh thrombosis, was responsible for vascular occlusion. In the remaining cases, a not always fresh thrombosis was encountered and an underlying sclerosis was always present. It is incorrect to attribute death to coronary thrombosis without indicating the underlying primary sclerotic disease of the arteries. Cardiac hypertrophy was found in 117 of 163 subjects. It was more prominent in the presence of myocardial fibrosis.

Streptomycin in Tularemia.—Berson and Harwell state that of 56 patients with tularemia treated with streptomycin in Veterans Administration hospitals 15 were examples of pleuropulmonary tularemia. The pleuropulmonary infection occurred as a complication of the ulceroglandular form of the disease in only 5 cases. In the remaining 10, no primary site of infection other than the lung or the pleura could be determined. Streptomycin, when administered after the twelfth day of illness, appears to have little effect on the course of suppurative lymphadenopathy. Liquefaction and spontaneous drainage of lymph nodes may occur in such circumstances, even though there is striking improvement in the other manifestations of the disease. Only 3 patients demonstrated sensitivity to streptomycin. In none of these cases was it necessary to discontinue the drug. Streptomycin was highly effective in the treatment of tularemia in every case in this series. Its effect was most dramatic in the acutely ill patient pursuing a stormy course. The total dosage used in the 56 cases varied from 1.9 to 20 Gm., averaging 8.1 Gm. There was no difference in the dosage used in the ulceroglandular and the pleuropulmonary cases. The duration of treatment varied from four to eighteen days, averaging 9.1 days. Patients with the pleuropulmonary form of the disease were treated an average of two days longer than those with the ulceroglandular form. No correlation between the duration of treatment and the completeness of recovery could be observed.

Procaine Penicillin G in Oil: Its Use in Pneumonia.—Boger and his associates say that procaine and penicillin G are combined in equimolecular quantities to form a crystalline salt relatively insoluble in water. These procaine penicillin crystals were suspended in both cottonseed and sesame oils so that each 1 cc. of material contained 300,000 units of penicillin and 125 mg. of procaine. Both preparations were employed in this investigation, procaine proving superior by reason of greater stability and fluidity. No local pain of systemic toxicity was observed in 50 patients to whom procaine penicillin G has been administered. The duration of penicillin plasma concentrations above 0.039 unit per cubic centimeter varied from six to thirty hours in a group of 9 ambulatory controls. In a group of 10 patients with pneumonia it varied from seven to seventy hours. The averages in the two groups were twelve hours and thirty-three hours, respectively. Eighteen of 23 patients with bacterial pneumonia recovered without complication following a single intramuscular injection of procaine penicillin G in oil. Two patients relapsed under this therapy and 3 failed to respond. On the basis of these preliminary data, it appears that a single injection of 300,000 units of procaine penicillin will, in the average patient, give assayable plasma concentrations of penicillin, or a suppressive antibacterial action, for at least twenty-four hours.

Myocardial Changes in Fatal Diphtheria.—Gore points out that the high incidence of diphtheria in portions of Europe constitutes a medical hazard to this country under modern conditions of communication. The introduction of large numbers of United States troops into areas where the endemic diphtheria rate was high resulted in a striking increase of the incidence of that disease among them. This report is based on records and slides of 221 fatal cases of diphtheria accumulated at the Army Institute of Pathology. Material from the heart was available for review in 205 of these, and 143 of the 205 cases involved myocarditis. A higher mortality in the presence of myocarditis largely explains why its incidence in postmortem studies is so much greater than in clinical reports of diphtheria. As the length of survival from the onset of diphtheria increases, the incidence of myocarditis rises. A similar time relation is true for neuritis. Postdiphtheric neuritis appears later and is less frequent than myocarditis. The hearts of patients with myocarditis are dilated, with flabby, pale, or mottled musculature. Frequently the hearts are enlarged. Microscopically, there is a primary toxic degeneration of the myocardial fibers. The inflammatory response, which culminates in scarring, appears to be secondary to the muscle injury. In one third of the cases the manifestations of myocarditis appeared at a time when the patient seemed to be well on his way to convalescence. The importance of administration of antitoxin early and in adequate quantities is reemphasized as a measure to prevent myocarditis (and neuritis). A shocklike state following diphtheria must be recognized as a frequent manifestation of myocardial weakness lest the vigorous administration of intravenous fluids to combat it result in a fatal termination.

Roentgenologic Aspect of Sarcoidosis.—Ackerman points out that sarcoid lesions of specific organs were thought to be separate disease entities and were described under various names depending on their localization, until greater experience led to recognition of these entities as a generalized disorder affecting the skin, lymph nodes, uveal tract and parotid gland, lungs and skeletal system. Recent observations tend to show that visceral organs are perhaps more frequently involved. The authors observed 19 cases of pulmonary sarcoidosis during the last three years in members of the armed forces. The 19 patients manifested practically no clinical evidence of disease and were detected usually in the course of routine examinations. The mediastinal and pulmonary lesions show fluctuations characterized by regression of the enlarged nodes and dissemination and less conspicuous regression of the pulmonary infiltrations. These may appear as miliary, nodular and occasionally confluent patchy densities scattered over large areas of the pulmonary parenchyma. There is no definite correlation between the morphologic changes and clinical symptoms produced by them. Absence of significant mediastinal adenopathy does not necessarily rule out pulmonary sarcoidosis or prove that these nodes are free from the disease. A previously existing adenopathy may have regressed sufficiently so that it is no longer recognizable. In view of the clinical experiences the prognosis in cases of pulmonary sarcoidosis should always be guarded. A definite diagnosis of sarcoidosis can be established only by a biopsy.

Heberden's Nodes.—Stecher and Hauser say that observations on nearly 7,000 persons revealed that Heberden's nodes were nearly ten times as common in women as in men, more common in white persons than in Negroes and that the incidence was definitely related to age, being rare in young persons but affecting about 30 per cent of white women in the ninth decade. It was further demonstrated that the occurrence of this form of degenerative disease of the joint was strongly influenced by heredity. The present study is based on observations, case histories, photographs and roentgenograms of over 100 patients with Heberden's nodes and on material assembled during the course of previous studies. The appearance of the nodes may range widely from Heberden's original description of "hard knobs about the size of a small pea." They may start as a fluctuant swelling, a myxomatous subcutaneous cyst or a synovial lesion in the skin, but develop from these to large bony deformities. Roentgenograms reveal enlargement of the ends of the bones with distortion of joint space and irregularity of the joint surface. Large spurs develop from the attachments of the flexor and the extensor tendons to the terminal phalanx. Such spurs seen only in lateral views have been heretofore largely overlooked. The distal ends of the middle phalanges undergo change of the bony structure with irregularity and a foamy arrangement of the trabeculae. Heberden's nodes, typical manifestations of degenerative joint disease of the terminal finger joints, are sometimes associated with degenerative joint disease of the proximal interphalangeal joints. Such association was noted in 40 per cent of the cases reviewed. Degenerative joint disease involves periarticular soft tissue, tendinous attachments and subchondral marrow spaces as well as the joint cartilage and the immediately underlying bone.

Adenoma of Bronchus.—Naclerio and Langer point out that during the last decade an increasing number of bronchial adenomas have been discovered, the condition now being recognized as a definite clinical and pathologic entity. This tumor accounts for approximately 80 per cent of the benign bronchogenic growths. No unanimity of opinion exists regarding its origin, potential malignancy, relationship to cancer of the bronchus and its treatment. The disease is usually asymptomatic in the early stages, but not infrequently a dry, irritating cough is present. Hemoptysis is a cardinal symptom. As the tumor encroaches on the lumen of the bronchus, symptoms of partial or total obstruction may appear. Dyspnea is a frequent symptom. There have been episodes of pneumonia characterized by cough, mucopurulent sputum, fever and pain in the chest. As the tumor progresses, filling the lumen of the bronchus, destructive effects with irreparable damage to the lung develop so that the clinical picture is then one of either atelectasis, bronchiectasis, pulmonary abscess or empyema. The diagnostic procedures include plain roentgenography, section roentgenography, bronchography and bronchoscopy, the last being still the most decisive single diagnostic procedure available. The authors evaluate radiation therapy, bronchoscopic and surgical treatment. Case histories of 15 patients treated and cured by pulmonary resection, 10 by pneumonectomy and 5 by lobectomy are presented. Bronchial adenoma should be treated either by lobectomy or by pneumonectomy.

Osgood-Schlatter's Disease.—Although Osgood-Schlatter's disease (osteochondrosis of the tibial tubercle) is regarded as comparatively rare, Kridelbaugh and Wyman observed 13 cases of this disorder in the short period of nine weeks at a large Naval recruit training center. Nine of the patients gave a history of trauma. Most authors are of the opinion that conservative treatment with posterior splints, cylindrical casting, taping or ace bandaging over the tubercle and/or bed rest is the treatment of choice in early cases. The consensus favors a trial of such treatment before more radical measures are attempted. In the cases in which symptoms persist beyond four to six months under conservative therapy, there should be operative intervention. In the 13 cases reviewed here conservative treatment was employed while the patients were ambulatory and without restriction of their activity. Six of the patients showed improvement while the anterior part of the thigh was taped, 2 were not improved, 2 were made worse and 3 could not be followed. Making a rough estimate of the incidence of Osgood-Schlatter's disease on the basis of their material, the authors believe that the disease may occur in 0.14 per cent of males between the ages of 17 and 19.

Initial Manifestations of Pulmonary Tuberculosis.—Routine periodic examinations of 344 persons who had been under observation because of a history of contact with a known case of tuberculosis provided the principal source for this study conducted by Reisner. Roentgenologically demonstrable lesions developed during the course of observation. In 248 patients the initial lesion was demonstrated within twelve months after a previous normal roentgenogram and in the remainder the interval was longer than one year. In white persons pulmonary tuberculosis usually begins as a small localized lesion. In nonwhite persons the disease often begins abruptly and reaches extensive proportions within a short time. The roentgenologic aspects suggest that the early manifestation of pulmonary tuberculosis is usually a lesion of predominantly exudative, pneumonic character. The usual roentgenologic manifestation of the early tuberculous lesion of limited extent is a localized small area of "soft" infiltration, ill-defined and of flocculent appearance. The circumscribed infiltrates were observed only in a few cases. In about 90 per cent of the cases the initial lesion was located in the so-called vulnerable zone of either the right or the left lung, an area comprising approximately the upper third of the pulmonic field. Most patients with early minimal pulmonary tuberculosis have no symptoms, and the only method available for detection of the truly incipient tuberculous lesion is routine roentgen examination of the chest at periodic intervals.

Behavior of Initial Tuberculous Lesion.—Reisner discusses the evolution of pulmonary tuberculosis in 340 cases in which roentgenologically demonstrable lesions had developed during the period of observation. Sixty-nine per cent of the patients were observed for more than two and up to ten years after the initial detection of the pulmonary lesion. The remainder were observed for less than two years. It was found that the initial lesions are nearly always unstable and that they exhibit a tendency to progression. The cumulative rate of progression, calculated on the basis of person-years of observation, amounted to 59 per cent in white persons and 88 per cent in nonwhite patients. The majority of destructive forms of pulmonary tuberculosis seem to have their origin in inconspicuous early minimal lesions. There is apparently no way of predicting the subsequent evolution of the incipient minimal lesion other than observation over a considerable period of time. Consistent differences were observed between white and nonwhite persons as regards the mode of onset, the course and ultimate outcome of the disease. Its greater severity in the nonwhite group is indicated by a greater frequency as well as a more rapid tempo of progression and by a case fatality rate four times higher than in white persons. The serious potentialities of minimal incipient lesions of pulmonary tuberculosis indicate the need for careful therapeutic management and extended follow-up.

Uteroscopy: Preliminary Report on New Developments. L. P. Belous and J. S. Rubin.—p. 165.

Treatment of Cirrhosis of Liver.—According to Morrison it is now a decade since Patek introduced the modern therapy of cirrhosis of the liver. Some confusion has arisen as to (1) which lipotropic agents to employ in the treatment of a patient with cirrhosis of the liver (choline, methionine, liver extract), (2) the reason for failure of treatment in some 50 per cent of patients, plus (3) some method of determining the prognosis. The author presents an analysis of 35 patients with hepatic cirrhosis of the nutritional deficiency type associated with chronic alcoholism. These patients were treated either by a modified Patek regimen or by a diet high in protein, high in carbohydrate and low in fat, oral choline, and parenteral aqueous, filtered liver extract. These patients were treated from 1940 to 1947. For comparison a "control" series of 20 patients is also presented who were treated from 1938 to 1940 by the then current use of mercurial diuretics and ammonium chloride with paracentesis for ascites, and a high carbohydrate diet with glucose intravenously for the cirrhotic patients with ascites. An additional 22 patients with hepatic cirrhosis not associated with nutritional deficiency or alcoholism were studied for comparative purposes. An attempt is made on the basis of liver punch biopsies to clarify the forms and stages of hepatic cirrhosis which were responsive to treatment and those which fail to respond to treatment. The results of the outlined therapy in the early stages of alcoholic cirrhosis of the liver were excellent; in the moderately advanced stages of alcoholic cirrhosis they were good. In the advanced (Laennec's) stage of alcoholic cirrhosis the treatment was a failure. The results of the outlined therapy in nonalcoholic cirrhosis of the liver were poor.

Oxygen Therapy in Poliomyelitis.—Kubicek and his associates point out that of the 73 adult patients with bulbar poliomyelitis admitted to the University of Minnesota Hospitals, 39 were treated by tracheotomy for partial or complete obstruction of the airway. It was necessary to use a mechanical respirator on 21 of the 39 patients, because of failure of the central or peripheral respiratory mechanism. The construction and operation of a tracheotomy inhalator is presented. This apparatus provides humidification of the inspired air and has simple arrangements for the optional use of positive pressure during expiration and for increasing the positive pressure on inspiration as an emergency maneuver. Continuous use of the inhalator varied from four days to a maximal period of four weeks. The easily visualized excursions of the breathing bag and intermittent bubbling of the expired air through the manometer facilitated the watching of the critical patients.

Present Trends in Prepayment Medical and Hospital Plans. H. V. Mylee.—p. 45.

Hesperidin C for Capillary Fragility in Rheumatoid Arthritis.—In a group of patients with rheumatoid arthritis in whom capillary resistance was measured, Warter and his co-workers found 16 with borderline capillary fragility, 25 with severe capillary fragility and only 1 patient with normal capillary fragility. Forty patients with rheumatoid arthritis who had manifestations of abnormal capillary fragility have been treated and observed for three to twenty-four months. A combination of hesperidin 50 mg., a flavanone glucoside and ascorbic acid 50 mg., was found to be effective in restoring abnormal capillary fragility to normal in 90 per cent of the patients treated. Lemon peel infusion concentrate also restored abnormal capillary fragility, but a longer time and larger doses were required as compared to hesperidin C. Some patients showed fluctuations in capillary resistance due to acetylsalicylic acid, amphetamine sulfate, emotional stress and severe upper respiratory infections. Withdrawal of the drugs resulted in a rapid return to normal resistance. In patients with emotional stress and upper respiratory infection an increase in the dosage of hesperidin C maintained normal capillary resistance. High vitamin D and B complex therapy did not influence capillary fragility in the small group of patients used as controls. Protein hydrolysate with B complex did lower the sedimentation rate and favorably influenced the hemoglobin and red cell count, but there was no apparent beneficial effect on the abnormal capillary fragility. The authors suggest that hesperidin, a flavanone glucoside occurring in most varieties of citrus fruits, is essential for the absorption and retention of ascorbic acid, acting synergistically in maintaining normal capillary resistance. The correction of abnormal capillary fragility in patients with rheumatoid arthritis should be considered as only one of the phases to improve the patients' condition. This phase of treatment may enhance the efficacy of other therapeutic procedures.

Epidemic Infectious Hepatitis.—Volwiler and Elliott correlate clinical observations with laboratory data and liver biopsy histology in the late phases of hepatitis. Nine of 13 patients had persisting active hepatitis proved by needle biopsy four to forty-two months after the onset of jaundice. The remaining 4 had shown continuous mild clinical icterus eighteen months to twenty-one years following an illness typical of epidemic infectious hepatitis. The authors stress that late manifestations of epidemic infectious hepatitis include: (1) prolonged mild hepatitis which may last for several years without significant scarring; (2) progressive hepatic fibrosis associated with similar smoldering inflammation, and (3) continuous mild jaundice with normal histologic features and without abnormal liver function tests. Most likely to reflect persisting active inflammation are the 5 mg. sulfobromophthalein sodium test, the thymol turbidity test, the thymol flocculation test and the erythrocyte sedimentation rate. In cases of prolonged infectious hepatitis deep liver biopsies, such as may be obtained by trocar, are necessary for accurate evaluation of the state of the liver, and the histologic information obtained thereby is often essential to planning an intelligent therapeutic program.

Amebiasis in Veterans of World War II.—From January to August 1946, 12,000 patients were admitted to Hines Veterans Hospital; 58 of these were suffering from amebic colitis or its complications. In the last year before the war, of 9,000 admissions to this hospital only 8 were diagnosed as amebic colitis. The postwar incidence of this disease is therefore increased five times. All the cases were seen among veterans of World War II, although the general admission to this hospital includes a considerable number of World War I veterans. The authors observed a relationship between the exposure in tropical climates and the incidence of the disease. Fifteen cases of hepatic complications, indicative of a virulent infection, were observed in the 58 patients. The treatment of choice for hepatitis is emetine, and emetine plus aspiration for hepatic abscess. The wisdom of using emetine in carriers is doubted; the intestinal amebicides produce excellent results and are without danger. They do not require hospitalization of the patient. One case of amebic colitis complicated by a cerebellar abscess is reported, the second in the literature.

Effects of Insulin on Metabolism of Vitamin C.—Sherry and Ralli investigated the mechanisms by which insulin causes a prompt fall in plasma and urinary vitamin C levels. Insulin caused these changes regardless of whether it was injected subcutaneously, intravenously or intramuscularly. There were significant differences in both the onset and duration of the effects of insulin on both the plasma levels and excretion of vitamin C, depending on the route of administration of the insulin. The effects of the insulin in each instance were transient and were followed by a period in which the plasma level and the urinary excretion were elevated. This was followed by a return of the vitamin C levels to normal. Studies in dogs, rats, guinea pigs and human beings showed that insulin had no effect in vitro and that insulin did not affect the synthesis of ascorbic acid. It is suggested that insulin causes a transient transfer of ascorbic acid from the plasma and extracellular fluid into the tissues, possibly for some catalytic function of ascorbic acid.

Heat for Inactivation of Virus of Serum Hepatitis in Albumin.—According to Gellis and his associates most epidemiologic investigations suggest that the risk of transmitting hepatitis is greater with plasma than with whole blood. This presumably depends on the practice of pooling the plasma from a number of donors, an occasional one of whom may harbor the virus, and of administering each pool to multiple recipients. The hepatitis viruses are known to be highly resistant to chemical and physical agents. They survive heating at 56 C. for one hour. They remain active for at least several years in the frozen state and withstand repeated thawing and refreezing. The remarkable thermal stability of human serum albumin solutions suggested the use of heat as the most likely method for the inactivation of the hepatitis virus. On the basis of limited experiments the virus of homologous serum hepatitis appeared to be inactivated when stabilized human albumin solutions to which the virus was added were heated at 60 C. and 64 C. for ten hours. This degree and duration of heating apparently do not seriously alter the measurable chemical or physical properties of the albumin. Heat treatment at 60 C. for ten hours in the final container is now a routine step in the preparation of human albumin solutions. Clinical use of albumin so prepared would appear to be free from the risk of transmission of active serum hepatitis virus.

Hydrazoic Acid.—Graham and his associates say that in the course of routine medical examinations in an explosives factory one of them observed that the workmen employed in the manufacture of lead azide showed considerable lowering of blood pressure. Clinical investigations were carried out on ten workmen. Determinations of the hydrazoic acid content of the air in the lead azide plant were made on separate days in the area of maximum concentration. The workmen stated that symptoms were noted only when the fume concentration was high. Then they experienced headache, palpitation, occasional weakness and unsteadiness. On cessation of exposure to the fume recovery from palpitation was almost immediate. Recovery from headache occurred in from a quarter of an hour to an hour and a half. Clinical and laboratory examination of the workers who had been regularly exposed to hydrazoic acid fume over a period ranging from one to fifteen years failed to reveal pathologic change which could be attributed to this exposure. Exposure to hydrazoic acid gas caused a rapid and severe fall in both the systolic and diastolic blood pressures, which was associated with headache. Animal experiments showed that hydrazoic acid in high dosage is extremely toxic. Hydrazoic acid and sodium azide, administered to animals in small doses, cause mild respiratory stimulation, a fall in blood pressure and coronary dilatation. Hydrazoic acid in concentrations which appear to have no permanent adverse effects is a powerful hypotensive agent.

Surgical Lesions of Left Colon.—Diagnostic problems of lesions of the left colon are numerous, the distinction between malignant tumors and tumefaction due to peridiverticulitis being the most difficult. Present methods of preparing patients for colonic surgical measures, especially the administration of sulfasuxidine and phthalylsulfathiazole ("sulfathalidine"), tend to decrease the mortality and the morbidity in this surgical field. During the period January 1946 to July 1947 resection of 23 carcinomas of the left colon were performed by Rosser without fatality, peritonitis or serious infection of the wound. Definitive indications for multiple stage removal of the colonic tumor, including partial obstruction and infection, were present in 7 cases. Exploratory operations for possible colonic polyposis are justified in the presence of inconclusive radiologic observations because of the serious potentialities of the lesion. The surgeon, not the pathologist, must determine how extensive the surgical procedure shall be when a polyp is discovered in the colon. Ten cases of stenosis of end colostomies were observed, apparently due to a low grade inflammatory reaction causing retraction. For the prevention and repair of this type of stenosis Cattell's method of skin inversion was employed, to which the Sturmdorf stitch was applied with a silkworm suture to hold the skin more firmly and effectively in place.

Endometriosis.—Counseller believes that there is no pelvic operative procedure that at some time is not required for endometriosis or made more difficult by its presence. Since the symptoms of endometriosis are due to the presence of functioning ectopic endometrium, castration may cure the majority of patients, the exception to this being cases in which the chief symptoms are due to a mass in the pelvis, obstructed loops of bowel or massive adhesions. The ovaries of patients of any age group should not be removed unless it is necessary, but especially not those of patients less than 40 years of age. In spite of strong convictions in this regard, it was deemed necessary to produce castration in 30 per cent of the cases in which patients were less than 40 years of age, because the extensiveness of the endometriosis precluded its complete removal. More than 50 per cent of the patients with moderate or severe symptoms and physical indications of endometriosis require castration to relieve their symptoms. Some patients have the endometriosis confined to one removable adnexum or this plus a few removable implants. Either the endometriosis or the ovaries must be completely removed in order to obtain a surgical cure. A high percentage of secondary and tertiary pelvic lapatotomies are required because an incomplete operation was done previously for endometriosis. If the extensiveness of the endometriosis is such as to require castration, the procedure is not usually followed by the same intensity of menopausal symptoms as is common in castration for other reasons; the gradual destruction of ovarian tissue by the endometriosis may have progressed at the time of intervention to such an extent that the patient has been bordering on menopause for some time. During this period she may have unknowingly made a gradual nervous adjustment which the final complete withdrawal of ovarian secretion does not upset. Presacral neurectomy was done in a selected group of 20 cases in which the chief symptoms of dysmenorrhea and dyspareunia were due to deep implants in Douglas' cul-de-sac which could not be removed. This was combined with excision of the accessible implants and usually a suspension of an adherent retroverted uterus. Owing to careful selection of patients the results of this procedure have been good.

Coronary Disease of Hip.—According to Chandler, infarction of the head of the femur presents a group of symptoms dominated by pain, loss of function and bony collapse caused by anoxemia and other deficiency in arterial nutrition of the head of the femur, prolonged enough to result in appreciable degeneration, even necrosis of bone. In many respects the sequence of degenerative pathologic changes following impairment of the circulation in the head and neck of the femur parallels similar processes in cardiac coronary disease. The degree of degeneration and the effectiveness of repair depend on the extent of the vascular impairment and establishment of an adequate collateral circulation. The possibility of the embarrassment of circulation through the vessels lying in the synovial folds of the femoral neck by increased joint pressure, caused by effusion, must be kept in mind. Loss of hip function corresponds with degenerative changes resulting from inadequate blood supply and the resulting lack of nutrition. The concept of "coronary disease of the hip" will afford a better understanding of many of the pathologic processes encountered in the head and neck of the femur.

Rupture of Papillary Muscle of Heart.—Davison reports 3 instances of spontaneous rupture of a papillary muscle of the heart in 2 men aged 55 and 63, respectively, and in a woman aged 69. Only 26 cases of spontaneous rupture of a papillary muscle of the heart have been listed in the literature and 2 additional cases were added by courtesy of personal communications. The condition is rare and defies diagnosis except at necropsy because of the almost immediate death of the patient following such rupture. Its antemortem diagnosis was established for the first time in 1 of the author's cases, in which the presence of a rough, harsh, systolic murmur and a questionable diastolic murmur, heard best at the mitral area and associated with the picture of myocardial infarction, strongly suggested the possibility of recently ruptured papillary muscle of the left ventricle. The great majority of spontaneous papillary muscle rupture occurred secondary to coronary artery occlusion and associated myocardial infarction, but in several instances a coronary artery thrombus was not demonstrated and arteriosclerosis of the coronary arterial tree was minimal. The disproportion between myocardial nutritional demand and coronary blood flow conceivably may be responsible not only for extensive papillary muscle necrosis in the absence of striking coronary artery disease, but may also exaggerate the myocardial lesions even in the presence of a thrombotic coronary artery occlusion. Coronary insufficiency may be the common denominator in spontaneous rupture of a papillary muscle with or without coronary artery occlusion. A meager collateral blood supply to the superficial bulbospiral muscle which forms the left posterior papillary muscle may be a contributing factor. The clinical diagnosis of a ruptured papillary muscle may be considered in a patient with evidence of recent myocardial infarction and with a change in the character and intensity of a murmur which antedated the infarction. The murmur is usually mitral in position and systolic in time, and becomes loud and harsh.

Retropubic Prostatectomy.—Lowsley and Gentile performed retropubic prostatectomy as developed by Millin of London in 28 patients. They found that this operation is possible in almost every type of prostatic obstruction, but they consider it feasible under the following conditions: in many cases of large adenomatous prostates that can be removed in one stage, when the patient's general condition does not warrant a traumatizing operation, when a shorter period of hospitalization is vital to the patient's health, and when, because of the patient's age, the maintenance of sexual function must be considered. The results of the operation are most gratifying. The authors have had no deaths, no persistent urinary fistula and no postoperative incontinence of urine. The patient's convalescence is more rapid and satisfactory than after any other type of prostatectomy and the period of hospitalization is substantially reduced. There is earlier urinary control than after other types of prostatectomy.

Retropubic Prostatectomy, Extravesical Technic.—Bacon says that since he saw retropubic prostatectomy demonstrated by Millin of London and van Gulik of Amsterdam he has performed the operation in 32 cases. He stresses that the operation is anatomically sound as no important organs are disturbed or endangered. All obstructing tissue is removed, thereby eliminating the risk of recurrence. There is practically no danger of postoperative or delayed hemorrhage, nor of persistent fistula, prolonged infection or urethral stricture. The procedure is done in a highly vascular area so that exact and prompt ligation of precapsular veins must be carried out. The postoperative period is relatively short. Retropubic prostatectomy avoids the disasters and indignities (rectourethral fistula, incontinence and impotence) of perineal prostatectomy. It is not applicable to prostatic fibrosis, bladder neck contracture or extensive carcinoma.

Dyspepsia in the Army.—Kraemer says that in the first World War a digestive neurosis was diagnosed in over one third of the patients admitted to the gastrointestinal service of a United States Army General Hospital. From the author's experience in station hospitals in the United States and a general hospital in the European Theater, despite more adequate roentgen and laboratory helps toward establishing a disease entity than were available in the last war, the incidence of psychoneuroses and allied disorders was as great or greater. The author comments on the high incidence of a history of dyspepsia in soldiers who were admitted to the neuropsychiatric service and on the reasons why many mentally unfit men in the Army were not recognized and eliminated. He is convinced that attempts at rehabilitation of persons with dyspepsia lead nowhere unless a special diet and protected existence can be provided. At best, these patients are fussy eaters. Numerous foods disagree with them. No regular army mess is adequate for them. A few might be retained as service personnel in large hospitals in the United States.

Treatment of Arterial Embolism.—Warren and Linton cite the various new measures that permit conservative treatment of arterial occlusion, such as intermittent positive and negative pressure, interruption of the sympathetic pathways, either surgically or otherwise, or the use of heparin. It was with these new treatments in mind that the authors decided to investigate what place, if any, embolectomy should play in the treatment of arterial occlusion. They investigated the records of 98 patients who had 172 arterial emboli during the period 1937 to 1946. Conservative treatment was available during the whole ten year period. In 1937 and 1938 the principal conservative methods used were papaverine, paravertebral procaine block and the pavex boot for the administration of intermittent suction and pressure. After 1939 the pavex boot gave place largely to intermittent venous occlusion and the oscillating bed. The use of the other conservative methods was continued. Since most of the nonoperative methods were used in combination, their efficacy cannot be evaluated individually. Twenty-one patients were operated on, 4 having two operations each. Four emboli were removed in 3 patients who died so soon that the effect of operation on the limbs could not be determined, but of 21 patients in whom results could be analyzed, 18 survived. In the 3 cases in which the limbs were lost there was technical difficulty in removing the embolus, in 2 cases because the clot was adherent to the artery. In nearly two thirds of conservatively treated arterial emboli the limb was preserved. Thirty-eight of the 98 patients died in the hospital. Although available conservative weapons are valuable adjuncts to surgery, surgical embolectomy is the treatment of choice in peripheral artery embolism.

Streptomycin in Acute Brucellosis.—Howe and Heyl review previous reports on the use of streptomycin in acute brucellosis. Because of equivocal results observed to date the authors present an instance of infection due to Brucellus abortus, in which streptomycin was used with some evidence of therapeutic effect. The patient was a man aged 52 who two weeks before admission had had a shaking chill, which was followed by daily afternoon elevations in temperature to 100 to 102 F. and profuse night sweats. He had consumed unpasteurized milk on numerous occasions. Streptomycin did not become available for use in this case until five weeks after the patient's admission, and a control period of observation in which no chemotherapeutic or antipyretic agents were administered was thus allowed. Fifty-eight days after the onset of the illness, a course of streptomycin was started. The patient was given a total of 60 Gm. in daily doses of 6 Gm. (1 Gm. every four hours) over a period of ten days. A review of previously reported cases of brucellosis treated with streptomycin indicates that patients in whom the highest blood levels of drug were maintained for even relatively short periods showed more signs of response than those in whom lower blood levels were maintained over relatively longer periods. Therapy at high dosage, however, is not without risk of streptomycin intoxication, as evidenced by the slight though definite vestibular impairment persisting in this patient.

Electroencephalogram in Epilepsy.—Abbott and Schwab investigated 193 patients attending the Epileptic Clinic of the Nerve Out-Patient Department at the Massachusetts General Hospital. Epileptic patients each showing at least one normal electroencephalogram between seizures and those showing only abnormal electroencephalograms between seizures were compared with reference to ten other aspects of the disease. All ten comparisons were favorable to the patients with normal records. In the patients with normal electroencephalograms there were later onset, fewer different kinds of spells, less frequent spells, greater response to medicine, more remissions while off medicine, more spells during sleep and greater ability to work, whereas patients with abnormal records had had spells in infancy, head injuries or other encephalopathies and positive family history of epilepsy.

Streptomycin in Bacterial Endocarditis.—Massell and his associates report the case of a girl, aged 9, in whom streptomycin proved effective in the treatment of endocarditis caused by a gram-negative organism belonging to the genus Hemophilus. The causative organism was isolated and its sensitivity to the drug in vitro determined before treatment was started. The concentration of streptomycin maintained in the blood was never less than twice and rose as high as fifteen times that required to inhibit the organism in vitro. A short intensive course of streptomycin eradicated the infection. The patient is perhaps first of this kind to recover without any other therapy than streptomycin, and the recovery followed a shorter course of treatment than would ordinarily be planned. Treatment was started with 2 Gm. of streptomycin daily, given in eight divided doses at three hour intervals by intramuscular injection. The patient improved during the first five days of treatment, until it became necessary to use a different brand of streptomycin. The second lot caused fever and local irritation so severe that treatment had to be discontinued after a total of only 13.5 Gm. had been given in six and a half days. The patient was well and active one year after the completion of therapy.

Malaria.—Warthin and his associates say that during the year of July 1946 to July 1947 125 patients with proved malaria due to Plasmodium vivax, all of Pacific origin, were admitted to the Veterans Administration Hospital, West Roxbury, Mass. All had received suppressive quinacrine therapy while stationed in malarial zones, and most had been given various doses of quinacrine for prior clinical attacks. Once a positive smear had been obtained, either of two methods of treatment was offered. Those who desired as short a period of hospitalization as possible were treated with chloroquine diphosphate. The dosage was 1 Gm. (four tablets, each containing 0.25 Gm. of the diphosphate) followed in eight hours by 0.5 Gm. (2 tablets). A single dose of 0.5 Gm. was administered on the second and third days of treatment. Most patients were discharged on that day, with instructions to take 0.5 Gm. (two tablets) every Sunday for five weeks. Patients who complained of over five recurrent attacks of malaria and those who were able to spend two weeks in the hospital were placed on the combined quinine-pamaquine regimen as outlined by Most and associates. Pamaquine naphthoate, in 0.02 Gm. doses, was administered every eight hours for fourteen days. Quinine sulfate was prescribed in 1 Gm. doses every eight hours for one day followed by 0.6 Gm. every eight hours for thirteen days. Follow-up examination was identical to that for patients treated with chloroquine. The authors found that chloroquine (SN 7618) is easier to administer and does not have the yellow dye discoloration effect of quinacrine. Clinically, it was no more effective in preventing relapses than quinacrine. The combined quinine and pamaquine regimen has greatly reduced the relapse rate.

Gangrene Due to Ergot Poisoning.—Loe presents the case of a man, aged 46, who was admitted to the hospital with gangrene of both feet. His present illness began twenty-one days previously, when he was undergoing treatment for jaundice and pruritus in another hospital. Approximately four days after the therapy was started he complained of burning sensations in his feet and legs, and the nurse discovered that both feet were turning black. His physician stated that he had given the patient six injections of "ergotrate" (0.2 mg. ergonovine maleate per ampule) over a period of three days, for the purpose of controlling a severe pruritus. The drug was discontinued as soon as the gangrene became apparent. Amputation was delayed because of the presence of arterial pulsations. Gradually the skin was exfoliated. The right foot healed without amputation, but parts of the toes of the left foot had to be amputated. The importance of recognizing the prodromal symptoms of ergotism cannot be overemphasized, for in this stage cessation of the administration of the drug and therapy can prevent irreparable damage. These symptoms are coldness, cramps and paresthesias such as tingling, numbness and burning. Paleness and mottling of the skin precede gangrene. Therapy should be directed at dilating the arteriolar vessels. Papaverine has been used successfully. Vascular exercises and reflex heat have also been employed. Use of heparin and "dicumarol" should also be of value in preventing or limiting the formation of thrombus. Theoretically lumbar sympathetic block should be beneficial when "ergotrate" is the acting agent but not when ergotamine tartrate is the offending factor, since the former acts centrally on the sympathetic nervous system and the latter on the myoneural junction. Development of gangrene does not call for immediate surgery. A period of waiting may demonstrate that a large part of the gangrenous area involves only the superficial layers of the skin. Reports indicate that relatively small doses of ergot may produce gangrene in persons who are susceptible to the drug.

Cancellous Bone Grafts for Nose.—Martin used cancellous bone for the restoration of the nasal contour in 15 cases. Six of these cases involved war injuries. The author uses the midcolumella incision because it gives the best exposure of the dorsum of the nose and the nasal spine of the maxilla. This incision makes it possible to dissect an adequate pocket for the strut. In undermining the dorsum of the nose an attempt is made to stay beneath the periosteum. An iliac crest is exposed and the cortical portion elevated with a saw. An appropriately sized block of cancellous bone is removed and shaped. A groove is placed in the posterior surface near the distal end of the graft which overlies the dorsum of the nose. The tip of the graft is elevated to the desired height and the length of the strut necessary is estimated. The strut is then cut off and fitted into the groove. The incision is closed and mattress sutures placed through the columella and tied over lead plates to relieve tension. Immobilization is effected by nasal packing and a nasal splint of lead plates. The grafts are usually secure in ten to fourteen days. The method was successful in all cases. The author feels that cancellous bone grafts are superior to autogenous cartilage. They are more easily secured; the site of the scar is well hidden and they are readily shaped and show no tendency to buckle or warp. They are more resistant to infection.

Roentgen Treatment of Multiple Myeloma.—Garland and Kennedy review the results of roentgen treatment of multiple myeloma as reported in the literature and in a series of 13 patients, 6 men and 7 women between the ages of 31 and 72 years, treated at the San Francisco Hospital. In the latter series the maximum tissue dosage to any one lesion, calculated to the middle of the principal tumor in the area treated, varied from 200 r in one day to 2,800 r in twenty days. Six of the patients showed improvement, 6 were not appreciably benefited and 1 had incomplete treatment. One of the patients survived over nine years and is still living; he is ambulatory and in good clinical condition, despite an initial grave paraplegia. The average survival for the remaining patients with proved myelomas treated roentgenologically was 10.4 months, while that of the untreated patients was only 2.3 months. These results are distinctly inferior to those of Batts, who reported a survival period of twenty-three months in an irradiated group and six months in an untreated group. This difference may be due to variation in the stage of the disease in the two groups, plus variation in the roentgen dosage in some of the authors' cases. Adequate irradiation of patients with multiple myeloma is still worth attempting, though the results will unquestionably disappoint those who accept commonly published statements that these lesions are "very radiosensitive."

Irradiation in Leukemia and Allied Disorders.—Hamann reviews 337 cases of blood dyscrasias in 203 men and 134 women treated by external irradiation in Billings Hospital, Chicago, during the period 1929 to 1945. One hundred and ten patients had leukemia, 143 had Hodgkin's disease, 77 had lymphosarcoma and 7 had polycythemia rubra vera. In one group of patients in advanced stages of Hodgkin's disease and lymphosarcoma who had received extensive irradiation with decreasing response, treatment was carried on with nitrogen mustards (beta-chloroethylamines). A second group of patients with the same diseases, with or without previous roentgen therapy, were referred for local irradiation after nitrogen mustards had failed to decrease the size of large tumors. In an obese woman with a reticulum cell sarcoma confined to the pelvic lymph nodes, intravaginal application of radium followed external roentgen irradiation. In a patient in the final stage of Hodgkin's disease an analgesic effect was obtained with a radium mold. Roentgen therapy of leukemia, Hodgkin's disease and lymphosarcoma, judiciously given with the present methods, is an effective palliative measure with a great safety margin and few complications. It finds its broadest indication as local irradiation of the various foci of disease. The efficacy of total body irradiation as to a systemic effect and the effect on generalized and subclinical foci is less clearcut. It is in these respects that the therapeutic use of radioactive isotopes and chemical compounds might be advantageous, but the author's experience with nitrogen mustard compounds does not yet allow valid conclusions. The high dosage required for effective roentgen therapy of polycythemia vera does not allow frequent courses of treatment.

Ultraviolet Blood Radiation Therapy.—Miley and Christensen treated 79 consecutive patients who had acute virus or virus-like infections with ultraviolet radiation of the blood. The technic of this therapy consists of withdrawing approximately 3 per cent of a patient's total blood volume, citrating the withdrawn blood and immediately passing the citrated blood through a Knott hemoirradiator, which exposes the blood safely and efficiently to high intensity ultraviolet rays. The irradiated blood is then returned to the patient's venous circulation. All the 43 patient's with early and of the 27 with moderately advanced infection rapidly recovered, and 8 of 9 of the apparently moribund ones. The subsidence of toxic symptoms in patients with poliomyelitis of bulbospinal and spinal type, with primary atypical or "virus" pneumonia, with mumps and with acute herpes, occurred with striking regularity within twenty-four to seventy-two hours. No ill effects were noted. The mechanism by which this method acts is not definitely known, but it seems highly probable that the resistance of the host is raised rapidly and efficiently by a direct stimulating and energizing effect after the intravenous induction of ultraviolet energy. It is strongly suggested that ultraviolet irradiation of the blood may be observed to be the ideal method of controlling acute virus or virus-like infections safely and efficiently.

Pathogenesis of Adenomatous Polyps.—According to Bacon and Broad, five factors point to a close relationship between intestinal adenoma and cancer: Intestinal adenomas develop into the malignant state in a significant proportion of cases. The appearance of adenomas precedes or accompanies the general cancer age group. The sigmoid and rectum contain the greatest numbers of carcinomas of the large bowel; the frequency of the location of intestinal adenomas is likewise the greatest in the same area of the large intestine. There is a frequent coexistence of cancer and adenomatous polyps in the same person. A patient who has the inherent tendency toward having intestinal adenomas may have one or more of them, cancer in the same region, or various combinations of both. Intestinal adenomas are to be considered as premalignant lesions and should be treated by destruction or removal.

Pediatric Approach to Tonsillectomy.—Glover believes that pediatricians should approach the problem of tonsillectomy with caution. The incidence of tonsillectomy remains excessive, particularly in children between 5 and 7 years of age. This age distribution suggests that many tonsillectomies are performed because of enlargements which are either physiologic, associated with the great changes in development during this critical period, or immunologic responses to the unaccustomed infections met with on entry to school or to the sepsis resulting from the decay of the primary teeth. Tonsils cannot be determined as "diseased" or "infected" by clinical examination. As their function includes the arrest of pathogenic organisms, the fact that these can be found in them is no justification for operation. Tonsillectomy should command the respect due to a major operation. In some cases it is followed by unpleasant sequelae. It has a mortality which, though small, is larger than is generally appreciated. Tonsillar remnants may be more harmful than the original tonsils. The most reliable indication is the occurrence of frequently repeated attacks of acute tonsillitis which cannot be explained by extraneous infection. Indications such as frequent colds, chronic nasal catarrh and otitis media are misleading. To remove the tonsils to cure sinusitis is to put the cart before the horse. Certain other conditions including bronchitis, asthma and nephritis are definitely contraindications. The value of the operation in benefiting acute rheumatism is doubtful. The incidence of otitis and mastoid disease is the same or perhaps slightly increased in the tonsillectomized, while their liability to bronchitis and pneumonia is increased.

Vitamin D in Cutaneous Tuberculosis.—Dowling and and his associates report 44 cases of lupus treated with calciferol. Of the 34 adult patients, 30 have been discharged free from clinical evidence of lupus, and in the remaining 4 treatment is being continued. Of the 30 patients who have been discharged, 8 at some time showed signs of relapse. These relapses have responded well to further treatment. Many of the adults appeared to be worse during the early weeks of treatment with increase in redness and swelling and occasionally spontaneous ulceration. This was followed by gradual subsidence, pallor, and shrinkage of inflammatory swelling. Evidence of tuberculosis has disappeared in 7 of 10 children treated with calciferol; in the other 3 treatment is being continued. Calciferol was given also to 31 adults with noncutaneous tuberculosis. Most of them had tuberculous adenitis of the neck. Tuberculous tenosynovitis, peritonitis, bladder disease, dactylitis and disease of various joints were also treated. The results have been good, particularly with the lymph nodes. Subsequent excision has been made easy. Calciferol appears to have no direct action on the tubercle bacillus. It has an effect similar to that of the

Gerson-Herrmannsdorfer diet, cod liver oil, heliotherapy and light baths—in all of which the common factor is a relative abundance of vitamin D—but it produces this effect far more rapidly and completely than the older methods. Since local manifestations of tuberculosis are part of a general disease, the patient requires good food, fresh air and adequate rest.

Sympathetic Nerve in Cancerous Pain.—According to Dargent, pain-relieving operations on the sympathetic nerve in patients with evolutive carcinoma have been widely discussed. The inquiry he started in 1940 under the direction of Leriche has enabled him to gather anatomicopathologic data, to define the clinical features of sympathetic pain and to determine the limits of such operations. At first, the author performed after a successful cocaine infiltration test, surgical sympathetic nerve resections. Since only temporary relief was obtained, he gave up this operation, as he found that repeated cocaine infiltrations had produced more lasting results. He has performed over 300 infiltrations of cervical, thoracic and lumbar portions of the sympathetic trunk. He injects from 20 to 40 cc. of a 1 per cent solution of "scurocain" (procaine hydrochloride). Anatomic studies revealed that lesions are to be found in the sympathetic trunk and ganglions, as well as signs of reaction in the arterial wall in contact with cancerous lymph nodes—which explains the sympathetic origin of pain in some cases of evolutive cancer. The involvement of the sympathetic nerve in pain due to compression or involvement of peripheral nerves and pain produced by periosteal lesions is of a more accessory character. The pain is greatly relieved by cocaine infiltrations of the sympathetic trunks. This procedure, which is simple, should be preferred to operations on the sympathetic nerve.

"Temporal Arteritis."—The disorder appears mainly in persons over 60 years of age. Severe protracted headaches and signs of inflammation of the temporal arteries often appear early and facilitate diagnosis, but it seems that the term "temporal arteritis" is inadequate. Although inflammation of the temporal arteries has characterized nearly all the cases described, the whole aspect has been that of a prolonged general infection with widespread, if patchy, arterial involvement. Jennings believes that this condition probably occurs more frequently than is suggested by the approximately 44 cases hitherto reported in the literature. Four recent cases illustrate the chief features of "temporal arteritis," such as its occurrence in the aged, the persistence and severity of the headaches, the protracted course, the widespread involvement of the arteries and pathologic aspects which suggest that the arteries are involved in a low grade inflammation which differs to some extent from other known forms of arteritis. Treatment is chiefly palliative; a combination of acetylsalicylic acid and phenacetin will give hours of relief in all but the most severe cases. The addition of diacetylmorphine or codeine will be required in the more severe cases to give sleep at night. Removal of a part of an inflammed temporal artery has been found to diminish the headache in some cases.

*Sulfaguanidine in Treatment of Cholera. C. L. Pasricha, B. M. Paul, A. C. D. Gupta and A. K. Das.—p. 518.

Antimalarials and Penicillin in Treatment of Malaria.—With a view of finding a treatment that will check the acute attack and also control the relapses of malaria, Deshmukh investigated the effect of quinine in conjunction with penicillin. Of the 6 successfully treated cases, 2 typical cases are reported. Penicillin seems to have a synergic action on quinine in the control of acute attacks of malaria. Penicillin in conjunction with quinine and quinacrine is believed to be useful in controlling quickly the acute attacks and the relapses. The treatment is based on the rationale that the usual specific antimalarial drugs control the erythrocytic stage while penicillin controls the pre-erythrocytic stage of the malarial parasite.

Sulfadiazine in Cholera.—Comparing the effects of the usual supportive treatment in 423 cholera patients with the results obtained when this treatment was combined with sulfadiazine in 425 patients, Pasricha and associates found that the death rates in the two groups were 9.5 and 8.2 per cent, respectively. Another series of 451 patients treated with sulfadiazine was compared with a parallel series of 463 treated with sulfaguanidine. The mortality in the sulfadiazine series was 7.9 per cent, whereas in the sulfaguanidine series it was 4.3 per cent. These results indicate that sulfadiazine has no appreciable effect on the mortality of cholera.

Sulfaguanidine in Cholera.—A series of 1,118 hospitalized cholera patients were treated with sulfaguanidine, and the death rate was 3.7 per cent. A parallel series of 1,170 controls were treated in exactly the same way but not given sulfaguanidine, and the death rate was 7.5 per cent. A series of 60 cholera patients were treated with sulfaguanidine in village homes. No supportive treatment was possible. The death rate in this series was 18.3 per cent, whereas in a parallel control series of 59 cases, the death rate was 40.7 per cent. Sulfaguanidine is thus of considerable value in the treatment of cholera.

*Tuberculous Primary Infection in 3 Children, Occurring in Connection with Fall into Highly Contaminated River Water. V. Gaustad.—p. 281.
Pathogenity and Changeability of Strains of Mycobacterium Tuberculosis. E. Lammela.—p. 292.

Tuberculosis Following Fall Into Contaminated River Water.—Gaustad reports observations on 3 children who accidentally fell into a river which was greatly contaminated with sewage. In 2 of the children erythema nodosum developed, with positive tuberculin reaction and pulmonary changes from four to five weeks after the accident. In the third child a positive reaction to tuberculin and hilar adenitis with pulmonary infiltration were found on examination ten weeks after the accident. There were no clues to any tuberculous source of infection within the children's families or kindergartens. The possibility of infection with tuberculosis on the occasion of the accidental immersion thus remains. The sewage from a sanatorium and from a nursing home for tubercular patients empties into the river about 300 meters upstream from the site of the accident. After inoculation of river water into guinea pigs, tuberculosis developed in several of the animals.

Twenty Years of Vaccination with BCG in Sweden.—According to Wallgren, vaccination with BCG was introduced in Sweden in 1927. The vaccine is given intradermally. To prevent inoculation of persons already infected with tuberculosis, a negative tuberculin test must be obtained prior to the vaccination. After BCG inoculation the person must be protected against virulent infection for from six to eight weeks. The dose used was 0.05 mg. Until 1947 more than 500,000 persons have been vaccinated in Sweden, and the frequency of the BCG vaccinations is increasing, so that during 1947 probably more than 250,000 persons have been vaccinated. There are no signs that the BCG bacilli have regained their original virulence. The duration of the immunity produced by BCG differs individually but lasts as a rule from five to ten years. It appears to give protection against the immediate results of a virulent primary infection, i. e., against the clinical primary tuberculosis, miliary tuberculosis and tuberculous meningitis, to a certain extent also against pleurisy and pulmonary tuberculosis with cavity formation as far as it is the sequel of primary tuberculosis of the lung. Not much can be expected from BCG vaccination as a prophylactic against late secondary tuberculous infections such as skeletal or renal tuberculosis and ordinary phthisis.

Toxic Reactive Changes in Nuclei of Leukocytes (Pseudo-Pelger).—Heckner describes peculiar nuclear changes in leukocytes, which were observed in 6 cases of enteritis or enterocolitis and in 1 case of typhoid. Morphologically the nuclear changes could not be differentiated from Pelger's nuclear anomaly of the leukocytes. However, whereas Pelger's nuclear anomaly is hereditary and permanent, in the cases under consideration the anomaly disappeared simultaneously with the symptoms of the enteritis or typhoid. Studies of the bone marrow and of the blood suggest a toxic cause of the nuclear anomaly. The change is not like an ordinary deviation to the left. Differentiation from true Pelger's nuclear anomaly is possible by watching the course of the disease. The author suggests that in blood pictures with decided deviation to the left, but without leukocytosis, a careful search should be made for the presence of pseudo-Pelger cells.

*Treatment of Leukemia with Roentgen Radiation, Arsenic and Urethane. S. Moeschlin.—p. 107.
*Transition from Boeck's Disease to Miliary Tuberculosis. Contribution to Problem of "Atypical" Tuberculosis. U. Frey.—p. 129.
Clinical Significance of Bicycle Ergometer Tests for Evaluation of Reduced Capacity for Work, with Remarks on Behavior of Lactic Acid in Blood During and After Work in Various Diseases. B. Jasinski.—p. 152.

Treatment of Leukemia.—Moeschlin states that urethane, arsenic and roentgen irradiation exert only a palliative effect on leukemia. One should try to limit treatment to urethane or arsenic as long as possible because administration of these drugs in therapeutic doses prevents mitosis of the pathologically degenerated cell groups. In contrast to roentgen irradiation it does not affect the erythropoiesis. Roentgen irradiation should be practiced in cases which from the beginning are not amenable to treatment with drugs or in cases which become refractory after prolonged treatment with drugs. Irradiation is a valuable supplement to the treatment with drugs in patients with a very large spleen or with extensive involvement of lymph nodes in spite of improvement of the blood picture. Urethane is the treatment of choice for chronic leukosis because the drug has no toxic effects. Its mode of action is probably that of an elective control of the karyokinesis of the pathologically degenerated leukemic cells and a stimulating effect on the erythropoiesis. Satisfactory results were obtained against chronic myeloid leukemia with continued oral administration of 5 to 15 drops of Fowler's solution (solution of potassium arsenite) three times per day. With this treatment the capacity for work was maintained in a woman for nine years. Urethane was administered by mouth in doses of 3 to 4 Gm. per day. In the majority of cases the decrease in the number of granulocytes began only after ten to fourteen days. In contrast to Paterson, the author used urethane for continued treatment in small daily doses of 0.5 to 2 Gm. to prevent a new increase in the number of immature cells in the blood after the leukocyte values had been restored to normal. Advanced cases seem to be benefited by this treatment. The terminal occurrence of paramyeloblastic leukosis which characterizes the transition of chronic myelocytic leukosis into an acute form cannot be prevented by any of the available methods of treatment. This applies also to the primary paramyeloblastic forms of leukosis in which temporary remissions may be obtained with arsenic and frequent blood transfusions.

Boeck's Disease and Miliary Tuberculosis.—Frey reports the case of a man aged 29 who died from tuberculous meningitis. The family history was negative for tuberculosis. Three and a half years before his death the patient had headache, respiratory difficulty and irritative cough; he was tired and his capacity for work was reduced. Large lymphomas of the hilus of the lung were demonstrated on roentgenologic examination, but the lungs and the heart were normal. The course of the disease was benign and the patient's general condition was hardly impaired. The patient became seriously ill three and a half years later, and death occurred fourteen days after his admission to the hospital. The necropsy revealed fibrous degenerated granulomas in the lungs, liver, kidneys and spleen which resembled those of Boeck's disease. In addition to these granulomatous foci with definite tendency to fibroid degeneration, typical fresh miliary tubercles were present in the same organs. Definite transition from Boeck's disease to typical miliary tuberculosis with the classic picture of tuberculous leptomeningitis was demonstrated on microscopic examination. In cases reported in the literature as Boeck's disease the entire organism has been affected because of hematogenous dissemination. Some of these cases showed considerable similarity to chronic miliary tuberculosis. The author's case supports the concept of the tuberculous etiology of Boeck's disease. From the pathologic point of view its differentiation from tuberculosis does not seem justified. The term atypical tuberculosis of Boeck's type is suggested. The prognosis of this form of atypical tuberculosis is not always favorable because of the possible change to miliary tuberculosis.

Investigation on Congenital Deformities of Extremities in Tyrol. Vera Erismann.—p. 50.
Extensive Subcutaneous Emphysema in Mild Infections of Air Passages. T. K. Gwan.—p. 59.

Connection Between Hepatic and Skeletal Defects.—According to de Roever-Bonnet malformations of the skeleton are met with in different types of hepatic disease. These skeletal disturbances occasionally resemble rickets clinically as well as roentgenologically. Results of animal experiments indicate that the presence of bile is necessary for the absorption of vitamin D in the intestine and that the liver plays an important part in the internal metabolism of vitamin D. It is probable that the liver also exerts a special influence on the metabolism of calcium. In a boy aged 15 who had been well up to the age of 14 cirrhosis of the liver was accompanied by osteoporosis. The second patient had been hospitalized for the first time in 1928, as an infant aged 9 months, with symptoms of hepatomegalia glycogenica. In later years he was repeatedly hospitalized on account of hepatic and osseous lesions. He is now 21 years of age and manifests an osteoporosis that has existed for years. The author concludes that in the presence of chronic parenchymatous disease of the liver attention must be paid to the development of osteoporosis, which requires special treatment.

*Treatment of Erysipeloid with Penicillin. T. A. J. van Doormaal.—p. 165.
Temporal Arteritis. G. F. van Balen and J. de Bruyne.—p. 170.
Epidemic Cerebrospinal Meningitis in the Army. J. W. Baunders and J. van der Veen.—p. 178.
"Blue Baby" with Congenital Stenosis of Pulmonary Artery. I. Boerema.—p. 184.

Penicillin in Treatment of Erysipeloid.—Van Doormaal points out that the disorder which is caused by Erysipelothrix rhusiopathiae appears in human subjects in different clinical forms: a benign form, which usually remains localized, a serious generalized cutaneous disorder and a septicemic form that may or may not be accompanied by cutaneous lesions and which may become complicated by endocarditis. There is an allergic form which may become complicated not only by endocarditis but also by arthritis, meningitis, lymphadenitis, optic neuritis, intracranial abscess and necrosis of bone. Since this generally mild disease may sometimes assume a serious form, penicillin has been used in treatment. The author observed 3 cases in which complete recovery was obtained following administration of a total dose of 500,000 units of penicillin, a dose of 20,000 units being injected every three hours. Treatment with penicillin seems to be superior to serum therapy and does not involve the risks of serum sickness. Although penicillin therapy has the disadvantage that it requires hospitalization, it should be used for the severe and prolonged cases.

Hydrogen Ion Exponent (*p*H) of Several Fluids Used in Bandaging. G. J. N. Vleugels Schutter.—p. 541.
*Folic Acid Therapy in Hematologic Practice. G. Houpst.—p. 557.
Influence of War and Season on Tuberculosis of Lymph Nodes in Rotterdam. M. Straub and H. E. Schornagel.—p. 563.

Folic Acid in Hematologic Practice.—The first of the 3 cases presented by Houpst concerns a woman, aged 48, who had achrestic anemia, anemia of the hyperchromic type with free hydrochloric acid in the gastric secretion. Liver extracts were without effect, but the administration of folic acid tablets effected rapid improvement and finally permanent recovery. The second case reviewed is that of a woman, aged 68, in whom granulocytopenia developed following intramuscular injections of sulfapyridine. Treatment with folic acid produced an increase in the leukocytic count, but because the supply of folic acid was short at the time, this increase could not be maintained. The third case was one of essential thrombopenia in a woman aged 50, in whose skin, particularly of the thighs, large blue spots developed spontaneously. In other regions small red spots developed. Examination of the blood revealed thrombopenia Treatment with folic acid, hydrochloric acid and reduced iron resulted in the disappearance of the bluish spots and in an increase in the thrombocytes. This increase could be maintained with the aid of folic acid, and the clinical symptoms of thrombopenia disappeared.

Isoimmunization in Pregnancy: Review. B. Broman.—p. 103.
*"Etiology of Toxemia of Pregnancy." S. Gagner, R. Grubb and S. Sjöstedt.—p. 105.
Megalocytic Anemia in Infants. G. Edgren and Elsa Segerdahl.—p. 117.
Myelomatosis with Marked Hepatic Changes. T. Frölander-Ulf.—p. 121.
*Papillomas of Renal Pelvis. Kaare Liavaag.—p. 131.
Disappearance of Polymorphonuclear Leukocytes on Stirring: Source of Error in Leukocyte Count. N. Andresen and E. Praetorius.—p. 134.

Etiology of Toxemia of Pregnancy.—Gagner and his associates observed that in 7 of their 22 cases of toxemia of pregnancy, the father belonged to blood group O, in 7 the mother belonged to the father's blood group and in 2 the mother's group was AB. They refute the statement made by Edlén and his associates that if the father belongs to the O group or if the father's and mother's blood groups are homologous or if the mother belongs to the AB group toxemia of pregnancy does not occur (*Nord. med.* **36**:2281, 1947), and they question the suggested desensitization therapy, namely, injection of serum from the father into the mother in presumptive cases of toxemia. The procedure, they say, may cause injury to the fetus and must be considered as contraindicated unless investigation excludes this possibility.

Papilloma of the Renal Pelvis.—Four cases are described. Liavaag says that in the first 2 cases, in which papilloma of the renal pelvis was considered preoperatively on the basis of the roentgenologic examination, hematuria dominated the picture; in the third case, in which secondary infection in the renal pelvis brought the patient to the physician, calcification in the tumor also suggested possible calculus, especially since infection of the urinary tract with stone formation frequently occurs in patients with double renal pelvis. The hematuria may be transient and of brief duration, as in the first case. Diagnosis before operation is often difficult. In the fourth instance, in a patient with a history of papilloma of the renal pelvis treated by nephrectomy without ureterectomy, constant hematuria and increasing anemia developed. A tumor in the bladder was removed by diathermy; microscopic examination showed cancer. Secondary papillomas may follow papilloma in the renal pelvis and often become maligant. Because of tumor spread to the ureter, treatment of papilloma in the renal pelvis should be nephrectomy with extirpation of the ureter, preferably with resection of the adjacent part of the bladder. Postoperative control should be continued for a longer time. Patients with papilloma of the bladder should be examined roentgenologically, with regard to primary papilloma of the renal pelvis.

Decompression Treatment with Miller-Abbott Tube in Paralytic Ileus. H. Jensen.—p. 189.
Tight Ligamentum Teres Hepatis as Cause of Abdominal Disorders. T. Francis and E. Lykkegaard Nielsen.—p. 190.

Medical or Surgical Treatment of Thyrotoxicosis?—Jervell and Klovstad state that there were no postoperative deaths and that postoperative reactions were slight in their 109 cases of thyrotoxicosis treated operatively with subtotal strumectomy in 101 and hemistrumectomy in 8. Follow-up of 107 of the patients for from one to eight years showed satisfactory results in 103. Follow-up of from one to eight years of 51 of the 55 patients with thyrotoxicosis who were given continued iodine therapy showed good results in 35. In preoperative treatment methylthiouracil is not superior to iodine, requires a longer time and should be reserved for patients who are hypersensitive to iodine and who do not react satisfactorily to iodine. Methylthiouracil in permanent treatment in 20 patients with thyrotoxicosis gave good results in 11 patients observed up to two years. Severe intoxications occur mainly in the first weeks of methylthiouracil therapy, so that it should be possible by close observation to lessen the risk. The treatment must be continued a long time and calls for constant control. To what extent permanent recovery follows is still an open question. For the present methylthiouracil should be used in cases where the patient's age or special complications increase the operative risk, in recurrence after operation, and in mild cases with doubtful indication for operation. In many of these last iodine also gives good results. Methylthiouracil treatment may gain ground when more is known about the late results of the treatment. Less toxic and more effective derivatives of thiouracil may come into use.

Osteochondritis Ischiopubica.—Nitter reports 5 cases of osteochondritis ischiopubica in children, 1 case of septic, 4 of aseptic type. The entity was first described by van Neck in 1925. In 1941, 54 cases had been published in the literature. With delay or disturbance in ossification in the ischiopubic synchondrosis friction is believed to occur between the ends of the bones, and the resulting hyperemia and neoformation of inferior bone tissue lead to the inflammation characteristic of the disease. Roentgenologically osteoporosis and formation of cysts are seen, with destruction of bone; after weeks or months signs of recalcification and regeneration of bone appear. The so-called aseptic forms generally recede without intervention. In the usual mild cases the patients should be kept as quiet as possible till the symptoms abate. Permanent disability does not result. In children in whom vague pain suggests disease of the hip joint but the roentgen picture is negative, disturbances in ossification in ischiopubic synchondrosis should be considered.

*Experimental Macrocytic Anemia from Oral Administration of Streptomycin, and Restoration of Blood Picture to Normal by Administration of Folic Acid. T. Lucherini and L. Schiavetti.—p. 65.

Anemia Due to Streptomycin Cured with Folic Acid.—Animal experiments carried out by Lucherini and Schiavetti on rats and chickens demonstrated that streptomycin administered orally produces anemia of macrocytic type and granulocytopenia with hypoplasia of bone marrow. It is suggested that this effect of streptomycin is due to its bactericidal action on the intestinal flora. The hematologic picture as well as that of the bone marrow was restored rapidly to normal by the oral or parenteral administration of folic acid. The results of these experiments proved that in rats and chickens the bacterial flora of the intestinal canal plays an important part in the synthesis of folic acid.

*Critical Study of Therapeutic Value of Streptomycin. C. Gernez, J. Minet, P. Nayrac and R. Pierret.—p. 131.

Therapeutic Value of Streptomycin.—Gernez and his co-workers treated 153 patients (70 of whom had tuberculous meningitis, 63 pulmonary tuberculosis, 7 infectious diseases and 13 miscellaneous infections) with streptomycin by intramuscular route. The dose varied from 1 to 3 Gm. per day in adults and from 1 to 1.5 Gm. in children. Satisfactory results were obtained with six as with three fractional doses per twenty-four hours. Rapid improvement resulted in 28 patients with tuberculous meningitis, but so far not 1 case of clinical recovery of more than five months' duration has been observed after the discontinuation of treatment. The prognosis of tuberculous meningitis with disseminated tubercles is less favorable than that of isolated meningitis. The disease is more severe in children than in adolescents and adults. The intramuscular administration of the drug seems to be as effective as the combined intramuscular and intraspinal administration. Permanent recovery was obtained in miliary tuberculosis, but the improvement did not protect the patient against meningeal complications. Streptomycin exerts a favorable effect on pharyngolaryngeal and tracheobronchial tuberculosis, but less regularly on recent ulcerocaseous pulmonary tuberculosis. Streptomycin is ineffective against fibrous tuberculosis of long duration and tuberculous empyema, but it has a decisive effect on cutaneous fistulas. The drug was well tolerated. Not a single strain of organism isolated before or after treatment with streptomycin showed a resistance to this antibiotic which would have been superior to 0.5 microgram in Dubos' liquid medium.

Acute Anemia of Newborn Caused by Subaponeurotic Cephalohematoma. G. Gil.—p. 855.
*Variations in Treatment of Congenital Luxation of Hip. E. Diaz Bordeu.—p. 871.
Use and Abuse of Treatment with Massive Doses of Vitamin D. C. Ruiz.—p. 877.

Physiologic Edema of the Newborn.—Ortega and Jimenez observed edema of various intensity in 94 per cent of normal newborn infants. Because of this high incidence and the absence of pathologic conditions, the authors regard this edema as physiologic. In order to determine degrees of intensity, and in order to eliminate arbitrary estimates, the authors employed the McClure-Aldrich test for hydrophilia, making three hundred and thirty-eight tests in 60 newborn infants. There was a strict parallelism between the outcome of this test and the hydrophilia time in the first ten days of life; during the first twenty-four hours the average time was 167 seconds; on the ninth day of life it was 700 seconds. The proteinemia in the mother, in the blood of the umbilical cord and in the infants does not show changes to explain this edema. The authors suggest that the edema might be due to circulatory changes.

Congenital Dislocation of the Hip.—Diaz Bordeu calls attention to deformities which develop as the result of prolonged immobilization in patients with congenital disolcation of the hips. These inconveniences can be avoided by a modification of the classic treatment which was employed in 7 cases. The same position is used, with two short boots of molded plaster which are joined together with a stainless steel plate. This permits free movement of the hip, with the advantage of less deformities and better sanitation. The results obtained up to now have been highly satisfactory.

*Streptomycin by Tracheal Route in Treatment of Pulmonary Tuberculosis. F. Musotto and G. Paparopoli.—p. 93.

Streptomycin in Pulmonary Tuberculosis.—Streptomycin in one daily dose of 100 mg. was administered with good results to 15 patients with pulmonary tuberculosis. The drug was given by the transglotid route, through a nasal sound. The effects of the 100 mg. dose are as good as those of a much larger dose when the drug is given by the muscular route. The transglotid treatment either reduces or suppresses tubercle bacilli and bacteria in the sputum and greatly improves the general and pulmonary condition of the patient.

Some Diseases of Blood Treated with Mustard Gas. P. Chevallier, Mrs. Lamotte, S. Brion and Sabouraud.—p. 97.

Hereditary Methemoglobinemic Cyanosis.—Codounis and his co-workers report 14 cases of congenital idiopathic methemoglobinemia in 8 men and 6 women between the ages of 6 and 80 years, combined with familial cyanosis in 8. The 14 patients were all members of one geneologic tree comprising four successive generations, with 1 in the first, 2 in the second, 4 in the third and 7 in the fourth generation. Hereditary methemoglobinemic cyanosis should therefore be considered along with other hereditary diseases of the blood such as hemophilia, congenital hemolytic disease and certain varieties of anemia. This new hereditary disease is bound to the mutation of a chromosome gene, of a disease of genotype, transmitted as a dominant characteristic according to Mendel's law. Hereditary methemoglobinemic cyanosis can be transmitted by men as well as by women without predilection for either sex. The term hereditary methemoglobinemic cyanosis is suggested to replace that of congenital idiopathic cyanosis or familial cyanosis, since this new term comprises the three principal characters of that anomaly of the blood: cyanosis as the dominant clinical symptom, methemoglobinemia as the pathognomonic spectroscopic character of the disease, and its hereditary quality which includes its congenital as well as its familial character. The condition must be differentiated from cyanosis due to drug intoxication or to enterogenous autointoxication which may be combined with methemoglobinemia, but the latter is temporary only and is not hereditary. Reduction of the methemoglobin was obtained in vivo and in vitro with high doses of ascorbic acid administered intravenously or by mouth; the same result was obtained with methylene blue.

New Method for Diagnosis of Hemophilia.—Soulier does not consider prolongation of the coagulation time as a specific guide in diagnosis of hemophilia. A more accurate method suggested by the author consists of measuring the residual prothrombin in the serum after the coagulation of the blood and after immersion in a warm bath for four hours. This measuring was done with blood withdrawn by puncture of a finger, but precise and specific results were obtained with capillary blood alone. The method was applied to 13 patients with hemophilia, 3 of them adults between the ages of 19 and 41 years and 10 of them children between the ages of 7 months and 9 years. Nearly the whole amount of plasma prothrombin was still observed in the serum separated from venous blood as well as in that separated from capillary blood. The serum was brought into contact with standard thromboplastin for one minute, standard citrated fibrinogen was added and the coagulation time was determined; it was always below 8 seconds whether venous or capillary blood was used. Thus the tissue thromboplastin had masked but had not corrected the coagulation defect. Results obtained in normal persons showed that the time was about 20 seconds for a serum separated from venous blood. It varied from 30 to 60 seconds for a serum separated from capillary blood. This shows that a considerable part of the prothrombin of the blood was consumed (82 per cent in capillary blood). The same results as in normal persons were obtained in patients with hypoprothrombinemia, in patients to whom heparin was administered, in patients with purpura not associated with thrombopenia and in patients with pseudohemophilia. In patients with severe thrombopenia the deficient consumption of prothrombin from venous blood was nearly identical with that in persons with hemophilia, while the consumption of prothrombin from capillary blood was corrected at least partially, since the coagulation time was inferior to the normal one, but always above 10 seconds, thus differing from that in hemophilia. This method is an aid to diagnosis of hemophilia in infants.

Generalities Concerning Penicillin. R. Tulasne.—p. 1.

*Late Results of Treatment of Acute Osteomyelitis in Adolescents with Penicillin. R. Fontaine and A. Grosse—p. 3.

Penicillin in Acute Osteomyelitis.—Fontaine and Grosse treated 12 patients, 7 boys and 5 girls between the ages of 4 and 16 years, with acute osteomyelitis of the long bones, with penicillin. Five hundred thousand to 1,000,000 units of the drug were given in fractional doses every three hours by intramuscular route. Recovery resulted in 5 patients in whom penicillin therapy was started immediately at the onset of the disease. There was no abscess formation, nor were there any bony lesions revealed on roentgenologic examination. Follow-up continued for five to twelve months. An abscess without involvement of bone occurred in 1 case in which treatment was initiated fifteen days after the onset of the disease, but complete resolution was obtained. In 3 cases the general condition of the patients on admission was grave. Penicillin therapy was started within forty-eight hours to five days after the onset of the disease. There was a rapid improvement in the general condition with lowered temperature. Although these patients were saved, a chronic course with abscess and sequestrums could not be prevented. In the last 3 patients, penicillin therapy was commenced at the onset of the disease and apparently a complete resolution occurred; no bony lesions were revealed on roentgenologic examination. Within three weeks to two months abscesses, extensive lesions of chronic osteomyelitis type and periosteal hyperostosis occurred in the absence of general symptoms, with few local signs and with fatal septicemia in 1. Penicillin is not the treatment of choice in acute osteomyelitis; it may save the life of a patient with severe disease, and it may increase the incidence of recoveries in mild disease, but it does not prevent the severe types of bone suppuration.

Question of Advisability of Resection in Doubtful Cases of Ulcer. P. Huber.—p. 89.

Development of Surgical Treatment of Pulmonary Tuberculosis. F. Spath. —p. 91.

Spontaneous Subcutaneous Rupture of Rectus and of Obliquus Externus Abdominis Muscles. Sinani.—p. 93.

*New Test for Effective Vagotomy in Ulcer Disease. F. Mandl and H. Mannchen.—p. 97.

Vagotomy for Ulcer.—Mandl and Männchen performed subdiaphragmatic vagotomy on 35 patients with ulcer of the stomach, duodenum or jejunum during the period October 1947 to February 1948. Hess and Faltitschek demonstrated in 1924 that total acidity as well as free hydrochloric acid were increased in patients in whom blockade of the sympathetic nerve was carried out by administration of procaine hydrochloride. A preponderance of the vagus resulting from the elimination of the sympathetic nerve was regarded responsible for this increase in the secretion of acid and in the motility of the stomach. Blockade of the sympathetic nerve was performed on 21 of the 35 vagotomized patients. Results showed that there was still further increase in the acid values of 3 patients in whom not all of the vagus fibers which pass to the stomach have been interrupted. There was no change of the acid values in the remaining 18 patients in whom all the vagus fibers on the right and on the left side had been interrupted. The absence of an increase in acid values after blockade of the sympathetic nerve in vagotomized patients is a useful test of completeness of the vagotomy from the anatomic point of view.

Book Notices

A Primer of Cardiology. By George E. Burch, M.D., F.A.C.P., Associate Professor of Medicine, Tulane University School of Medicine, New Orleans, and Paul Reaser, M.D., Instructor in Medicine, Tulane University, School of Medicine. Fabrikoid. Price $4.50. Pp. 272, with 203 illustrations. Lea & Febiger, 600 S. Washington Sq., Philadelphia 6, 1947.

These authors have attempted to perform the difficult task of writing a work on cardiology in less than three hundred pages. Considering the handicap that confronted them they have done well. They have presented some general anatomic considerations of the cardiovascular system. This is followed by a section dealing with the approach to the diagnosis of heart disease. The common types of heart disease are discussed, including the management and treatment of each variety. The final section of the book deals with the bedside diagnosis of the cardiac arrhythmias. Electrocardiography is disregarded. The authors refer the reader to monographs on this subject, apparently believing that this has no place in a primer. At the same time they refer to certain types of heart disease, for example infectious myocarditis, in which the diagnosis may be made only with the electrocardiograph.

In the section on physical signs of heart disease they dwell little on inspection, palpation and percussion. Auscultation, however, receives an undeserved amount of attention. Indeed, there is a discussion of the physical qualities of sound itself that adds little to the value of the book. There is a complicated equation having to do with sound which will mean little to the medical student, less to the student of elementary cardiology and nothing at all to the practicing cardiologist.

The authors state that the fourth heart sound, produced by auricular systole, is "not frequently heard on auscultation." It would be more correct to say that it is almost never heard on auscultation.

The authors' definition of a functional murmur is a bit confusing. It is usual to think of a functional murmur as one which occurs in the absence of structural alteration in the cardiovascular system. Yet the authors speak of the functional murmur due to the dilatation of the aortic or mitral ring. Surely the dilatation of the aortic ring is a structural change—a reversible one to be sure, but none the less structural.

The authors classify neurocirculatory asthenia as a cardiac dysfunction produced by a psychoneurosis. This may be true but will not be accepted without argument in some quarters, and it seems a bit inconsistent to suggest that the removal of foci of infection is good treatment for psychoneuroses.

The section on the management of congestive heart failure is obviously designed for the extremely severe cases. It is not wise to suggest that a diet containing less than 2 Gm. of sodium per day is necessary for the treatment of all cases of congestive failure. Such a diet is extremely unpalatable and, something that the authors fail to mention, is likely to cause vitamin deficiency. Such diets are usually reserved for the more extreme cases.

The section on the bedside diagnosis of cardiac arrhythmias is refreshing. It is usually assumed that the electrocardiograph is necessary for such diagnosis. The student seems to have lost interest in attempting to make such a diagnosis without the help of some precision instrument. Here the authors point out that it is quite possible to differentiate the arrhythmias in many instances without any instrumental help. However, their enthusiasm occasionally leads them astray. For example, it is seldom possible to differentiate, clinically, between the premature auricular contraction and the premature ventricular contraction. It is true that the pause following the premature ventricular contraction is usually longer than that following the premature auricular contraction, but the difference is a matter of hundredths of a second and one's fingers, ears or mind is not sufficiently acute to recognize this difference.

Also, the authors have totally disregarded the fact that the premature auricular contraction may under certain circumstances be followed by a complete compensatory pause. Indeed, one would conclude from the text that such a pause never occurred. In fact, it seldom occurs but it may and does occur rarely.

These examples of inaccuracies are more than likely due to the effort to save space. They probably represent the penalty that is paid for trying to crowd the subject into a limited number of pages. All in all the authors have turned in a good job on an extremely difficult assignment.

The Green World of the Naturalists: A Treasury of Five Centuries of Natural History in South America. Selected and Annotated with Biographical Sketches and Introduction by Victor Wolfgang von Hagen. Cloth. Price $5. Pp. 392. Greenberg, Publisher, 201 E. 57th St., New York 22, 1948.

This book is a collection of some of the most representative writings of twenty-five naturalists who studied and wrote of South America. Five centuries of the natural history of the "Green Continent" are unfolded in the words of Humboldt, Darwin, Bates, Tomlinson, Hudson, Beebe and Sanderson, to mention only a few of the illustrious adventurers chosen by Mr. von Hagen.

The author introduces the contribution of each with a biographic sketch of the men whose lives and work extended over a period from the beginning of the sixteenth century to the present time. The wonders of the "Green World" are fully described, together with the stories of the men who faced hardship and peril to write of them.

Tales of these hardy naturalist-explorers who pushed aside South America's frontiers, explored its dark brooding rivers, climbed the lofty Andes and struggled across scorching deserts and through dense jungles cannot fail to hold the reader's interest. How they substituted fact for fable, investigated the continent's natural phenomena, rediscovered rubber, painstakingly studied the plants and animals, measured the tides and charted the earth's surface makes a fascinating story of the penetration of the "Green Curtain" by a series of knowledge-hungry men down through the years.

The reader can live for a brief time with the fabulous people who existed behind the "Green Curtain" of the New World. He can see, through the eyes of the men who first saw it, and marvel at the strange plant and animal life that abounded there. For pleasant diversion, for an excursion into humid forests, along the broad Amazon, up into the coolness of the Andes and down again to torrid, treeless plains, this book is highly recommended.

Psychiatry for the Pediatrician. By Hale F. Shirley, M.D., Associate Professor of Pediatrics and Psychiatry, Executive Director of the Child Psychiatry Unit, Stanford University School of Medicine, San Francisco. Cloth. Price. $4.50. Pp. 442. The Commonwealth Fund, 41 E. 57th St., New York 22: Oxford University Press, Amen House, Warwick Sq., London, E. C. 4, 1948.

This book is the product of the author's experience in the study and treatment of patients brought to the Stanford University Pediatric Psychiatric Unit and of his efforts as a teacher of medical students and resident pediatric staff members to make a basic training in child psychiatry a useful part of their training for pediatric and general practice. "It is intended to be an introduction to the subject; a primer as it were."

The author has succeeded well in his announced intention to keep his language simple but has not succeeded quite so well in observing another of his objectives, brevity. For example, under basic concepts in child guidance he has a discussion of enuresis that is repeated under development and habit training. In both of these, he repeats all the timeworn and largely discarded medical treatments for enuresis, even including Kragnogorski's inhuman and ineffective method of giving 5 Gm. of salt at bedtime. At the same time, he advances the psychogenic factors in the cause and treatment of enuresis in such an uncertain and roundabout fashion that one gets the idea that he has little faith in it as an effective method of treatment or as a principal cause. The general lack of specific instructions and dogmatic conclusion in that part of the book which deals with known physical disease is perhaps a natural result of the author's greater experience and self confidence when he writes of those problems which are preponderately in the psychic rather than in the somatic area of his field.

The foregoing criticism is more than balanced by the fact that the book covers nearly, if not all, of the psychiatric problems of children as they present themselves in practice. These problems and the role of the physician in their solution are so well presented that this book will be of great value to every practicing physician.

If the physician lacks experience, it will give him a sound, basic working knowledge of child psychiatry. If he has much knowledge and experience in this field, he will be encouraged to continue his work with renewed confidence and effectiveness by the author's clear and convincing statements of the fundamental nature of the child's needs as he strives to become a reasonable adult. For example: 1. "A large proportion of the behavior problems with which physicians have to deal can be understood in terms of growth." 2. "That just as food, shelter and protection against injury and disease are necessary for physical health and growth, so a favorable cultural environment is indispensable for the development of a well-balanced and socially adequate personality." 3. "It is too early to tell how much of the present reported findings, conclusions and opinions in regard to the phychiatric aspects of certain physical disease will prove to be well founded."

This book should be in every pediatric library for direct reference and for its excellent bibliography.

Phtisiologie infantile. Par Pierre Lowys, médecin-directeur du Sanatorium Le Roc des Fiz. Préface du Professeur R. Debré. Paper. Price, 2120 francs. Pp. 716, with 220 illustrations. Éditions médicales Flammarion, 22 Rue de Vaugirard, Paris 6^e, 1947.

This well prepared French volume is compiled on the basis of the author's extensive personal experiences, as well as those of his teachers, colleagues and predecessors. It comprises seven major parts under the titles Generalities, the Clinic, Diagnosis, Medical Treatment, Pneumothorax and Collapse Therapies, Surgical Treatment, and Hygiene and Prophylaxis. A chapter is devoted to the Ranke evolution of tuberculosis in three stages, and the importance of exogenous and hereditary infection and contagion from man and animal are considered in greater detail. Resistance—racial, age, sex, as well as traumatic and operational—is reviewed. The principal forms seen in the clinic are presented, and the evolution and prognosis given due consideration. Under diagnosis, examination, tuberculin reactions, bacteriologic examination of the sputum, the blood, etc., are reviewed as well as roentgenologic and roentgenoscopic technics and findings. In differential diagnosis, the various types and confusions are elucidated. Air, rest, food, intellectual and biologic and chemical therapies are presented, including symptomatic remedies. The methods and complications of collapse therapy are detailed from all aspects, and surgical measures applied to treatment are well presented. Under hygiene and prophylaxis are included disinfection, general hygiene, B.C.G. and the place of tuberculosis prophylaxis with consideration of the preventorium and sanatorium.

This excellent volume on infantile pulmonary tuberculosis is a well printed and sufficiently illustrated general text by a capable author, with adequate general information on tuberculosis included to make it clear. It is intended for students and those who wish to brush up on the subject covered.

Anatomie radiologique normale: Optique radiologique et dépistage des erreurs de lecture des clichés. Par Henry Tillier, électro-radiologiste des hôpitaux d'Alger, Alger. Paper. Price, 600 francs. Pp. 233, with 350 illustrations. G. Doin & C^{ie}, 8 Place de l'Odéon, Paris 6^e, 1947.

This book is not intended to be an all-inclusive atlas. It does not attempt to give the detailed technics for taking roentgenograms for various parts of the body. The illustrations are nearly all line drawings which do portray clearly the contours of normal bones. The authors emphasize particularly that different degrees of rotation of an extremity or a part of an extremity may produce marked differences in the shadows cast by the bones which are being studied.

Although the greater part of the text is concerned with the bones and joints, roentgenologic anatomy of the gastrointestinal and thoracic organs is also included.

It is well to remember—and this text definitely emphasizes the fact—that in order to interpret the abnormal the physician must first be thoroughly familiar with the normal roentgenologic anatomy.

Organic Form and Related Biological Problems. By S. J. Holmes. Cloth. Price, $5. Pp. 169, with 1 illustration. University of California Press, Berkeley 4, California; Cambridge University Press, Bentley House, 200 Euston Road, London, N. W. 1, 1948.

Among the most evasive of solution among biologic problems are problems of how plants and animals attain and maintain their form and organization. In the small book which is being reviewed, S. J. Holmes, who was among the earlier biologists who labored with these problems, has developed historically many of the proposed hypotheses together with their defending or opposing arguments. He has also attempted to add to the story such recent biologic information as may contribute to the solution of the problem.

In the first chapter, entitled "The Problem of Organic Form," the author has presented in a general way the questions which are to be answered. Starting with the points of view of Pflüger and Roux, he continues with those of Child, Driesch, McDougall, Cannon and others. Fortunately he directs his discussion away from teleologies and entelechies.

In the following twelve chapters the author deals with specific fields of investigation which have contributed to our understanding of development. The first of these is entitled "Building Through Functioning." In this chapter he discusses the contributions of causal explanations of homeostasis and other physiologic phenomena to our understanding of the development and maintenance of organic form. In the next chapter, on "Competition as an Integrative Factor," he develops Roux's conception of the struggle of the parts in development. Chapter V deals with "Chemical Equilibrium and Organic Integration." Here the author attempts to show how equilibrium, at first a problem of a single cell, becomes a problem of increasing complexity as development proceeds. Chapter IX concerns the contribution of a knowledge of cancer to our understanding of development. Chapter X is called "Genes versus Gradients." Here the author concludes: "there is little to justify the conclusion that gene activities are directed by gradients and much evidence for the reverse relation." The final chapter, as may have been suspected, deals with the subject of "Recapitulation and Its Supposed Causes." The chapter is primarily a historical treatment, but some attempt is made to add a new genetic point of view.

To those who have not followed the historical development of the many hypotheses which have been advanced as explanations of various aspects of development, the book may be highly recommended. It outlines in a clear style the concepts of many investigators and it attempts to integrate them. The book may be recommended particularly to the physician who sees the value of a broad understanding of what a human body is and how it came or comes into being and how it is maintained.

Les embolies de l'artère pulmonaire et des artères des membres: Physiologie pathologique et traitment. Par René Leriche, professeur au Collège de France. Paper. Price, 150 francs. Pp. 127, with 5 illustrations. Masson & Cie, 120 Boulevard Saint-Germain, Paris 6^e, 1947.

The output of French medical literature reaching us since the end of the war is considerable. Perhaps the authors were using their literary efforts as an escape against the horrors and misery which they witnessed during the German occupation. Certainly they were shut off from any outside source of information, which, in the case of original thinkers, may be more help than hindrance. Nobody could accuse Professor Leriche, who has just published his fourth volume of lectures on arterial diseases delivered at the Collège de France, of not having any original ideas. The present monograph deals with emboli, both pulmonary and peripheral arterial, and his conceptions summarized in this volume are the basis on which vascular surgery is practiced in this country today. It has been often said that some of the author's conceptions were devoid of experimental proof or lacked clinical confirmation. There is nothing, however, in this small monograph which had not been confirmed in time by adequate clinical studies, mostly from this country. Vascular surgery owes an everlasting debt to Leriche, who by sheer intuition and in spite of meager facilities has advanced the functional point of view in the treatment of acute vascular occlusions. This monograph is a brief summary of his twenty year old labors in this field.

Queries and Minor Notes

The answers here published have been prepared by competent authorities. They do not, however, represent the opinions of any official bodies unless specifically stated in the reply. Anonymous communications and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted on request.

POLLEN EXTRACTS

To the Editor.—When pollen extracts have been prepared (ragweed, timothy, etc.) and sent through the mails in midsummer, should they be administered when the pressure of gas in the vial is such that it blows the piston out of the syringe?

Virginia M. Palmer, M.D., White Plains, N. Y.

Answer.—Any injectable solution packaged in cold weather and hermetically sealed will develop considerable pressure when the package is kept at a high temperature. This pressure should cause no concern. It is unlikely that any pollen extract would develop pressure through fermentation by living bacteria or yeasts and not show some visible turbidity. If fermentation was present, the extract would probably show considerable bubbling and foaming after the excess pressure had been released. The nature of the menstruum and preservative would give one some idea of any possible cause for decomposition. The question is best referred to the manufacturer of the extract.

POLIOMYELITIS

To the Editor:—During the summer of 1947 several patients had illnesses which could have been anterior poliomyelitis. The symptoms are mild, spinal fluid examinations were not diagnostic and residual paralysis was absent or minimal. We are, naturally, still anxious to make an accurate diagnosis in these cases and in similar cases in the future. Is it possible to make an accurate diagnosis following convalescence by titrating antibodies in the patients' serum? What laboratories do this work and what is the procedure for and cost of obtaining material?

M.D., Texas.

Answer.—During the summer of 1947, there were many thousands of such cases throughout most of the United States and Canada. Comprehensive laboratory and clinical studies of approximately 100 such patients indicated a diagnosis of anterior poliomyelitis, not only because the signs and symptoms were compatible with this disease but because (1) the virus of poliomyelitis could be recovered from the stools of many such patients, (2) characteristic changes in the spinal fluid were usually noted either during the acute stage or within three weeks of onset, and (3) attempts to isolate other viruses were unsuccessful. An attempt to confirm a diagnosis of poliomyelitis following convalescence by quantitating the virus-neutralizing capacity of acute and convalescent serums is not justified. The unreliability of this method may be explained by the fact that clinical poliomyelitis can be induced by several different immunologic types of the virus.

STATIC ELECTRICITY

To the Editor:—What is the explanation for the occurrence of static electricity in some persons and not in others? What measures can be employed to eliminate this phenomenon, especially with reference to light switches, bedding and door knobs? *M.D., District of Columbia.*

Answer.—Inherently there is no known physical reason for some persons to show static electric phenomena more than others. Factors such as moisture of skin, type of clothing (silk versus cotton), footwear, conductivity of soles of shoes and atmospheric conditions of humidity may make static effects more noticeable in different persons and indeed in the same person at different times. There are great differences in individual psychic reaction with respect to sensory electric shocks. Some persons seem to be "hurt" more by static sparks than others—furthermore, many persons are apprehensive about anything obviously electrical.

Static phenomena are always induced on relatively nonconducting objects. Good electrical conductivity instantly grounds any charges frictionally produced. The production of charge itself depends on the types of material rubbed together. One therefore expects static phenomena more from silk-leather, wool-wax or rubber, and rubber-concrete combinations. To avoid completely such effects, metallic contacts to ground or their equivalent should be provided. Parking lots have a flexible metal spring that brushes the automobile axles and carries static accumulations to the ground where drivers have to reach out and contact ticket collectors. Chains dragging below oil trucks accomplish the same purpose. The minute static accumulations that persons accumulate from scuffing carpets, removing silk garments, changing bedding or making up beds are absolutely harmless and trivial. Not so are possible contacts with light switches whose metal frames may not be properly grounded and hence may be at the power-line voltage above ground. A person touching such a faulty device, if he be well grounded himself as with damp shoes on a damp floor, or in water in a tub, may get the full voltage across a long bridge through his body with enough current flow to cause cardiac fibrillation or even worse. This, of course, has nothing to do with static.

HYPOSPRAY

To the Editor:—Please furnish information on the punctureless hypodermic needle and syringe. Has it proved practical and is it in general use? Is the "needle" an integral part of the syringe or can regular syringes be used with it? Who makes it? *M.D., Ohio.*

Answer.—The device to which this inquiry refers is probably "hypospray," which has recently received considerable publicity. This device operates on the principle that a stream of fluid ejected with high velocity through an extremely small opening can penetrate solid objects with considerable facility. This device consists of a metal tube surrounding a plunger which is pushed by means of a highly tempered spring against the fluid medicament contained in a metal cartridge. The fluid is rapidly forced through an opening of 75 to 80 microns in diameter located at one end of the metal tube. The end of the tube in which this opening is located is held against the skin, the trigger holding the spring is released, and the fluid in the cartridge penetrates the skin without pain and usually without leaving a readily visible mark.

The depth to which fluid can be injected by this device depends on the spring tension, the thickness of the skin and the viscosity of the fluid. The makers claim that it is impossible to give an accidental intravenous injection with this device. The device is still in the experimental stage and has not been marketed. Numerous investigations to determine its usefulness and limitations are under way, and until the results of these investigations become available, the use of "hypospray" cannot be recommended. The rights to "hypospray" are held by R. P. Scherer of Detroit.

MYASTHENIA GRAVIS

To the Editor:—A woman aged 34 has had myasthenia gravis for eight years, requiring neostigmine methylsulfate ampules daily. She is now seven months gravid and reports she has required no neostigmine for six weeks. Please advise regarding postpartum management. I anticipate that she will have some sort of severe withdrawal symptoms.

Lester J. Olson, M.D., Spooner, Wis.

Answer.—Many patients with myasthenia gravis who become pregnant have a partial or complete remission from the symptoms of myasthenia during the second or third trimester of pregnancy. The reason for this is unknown. Presumably the imbalance of the acetylcholine-cholinesterase reaction at the myoneural junction is affected by the pregnancy, possibly by some hormone elaborated by the placenta. All attempts to explain this restoration of function have resulted so far in failure. Extracts of the placenta have not favorably affected patients with myasthenia gravis, nor have endocrine preparations used in sufficient amounts to establish their effectiveness in producing bodily changes. Moreover, transfusion of whole blood from a woman seven months pregnant did not change the symptoms of a patient with myasthenia gravis.

Delivery of patients with myasthenia gravis who are in remission has been surprisingly normal, and in most cases there have been no withdrawal symptoms. Indeed the symptoms of myasthenia may not appear for two or three months after delivery, and then their appearance is gradual and not explosive. If symptoms of myasthenia develop within a few hours or days after delivery, these can always be controlled by intramuscular use of neostigmine methylsulfate. Ampules of 0.5 mg. of the drug should be injected one or two at a time, and they may be repeated at appropriate intervals until the symptoms of patient are under control. Subsequently, if the symptoms of myasthenia have reappeared, the patient should return to the taking of neostigmine bromide by mouth, a more satisfactory form of medication over long periods of time than injections given four times a day. One tablet of neostigmine bromide by mouth is roughly equivalent to 0.5 mg. of neostigmine methylsulfate by intramuscular injection.

POLLEN ALLERGY

To the Editor:—My wife, son and daughter have hay fever, and the daughter has asthma during the ragweed season. I have considered air-conditioning some of the home for their protection during the autumn months, but have not found an ideal arrangement. Please give information in this regard and state whether complete relief is obtainable from this type of procedure.

V. J. Horton, M.D., Calmar, Iowa.

Answer.—Air conditioning for relief of hay fever and pollen asthma may be merely a procedure of filtration to remove pollen grains or filtration and cooling for comfort. The commonest filtering machines are those that use "celotex" filters. Another uses the principle of electrical charge on particles. It filters by attracting charged grains of pollen to plates which have an opposite charge and which are coated with oil to which the grains of pollen adhere. These machines are designed for the average-sized sleeping room. The purpose is to deliver filtered air under slight positive pressure into the room so that there will not be any back leakage of unfiltered air into the room.

A number of manufacturers make air cooling apparatus which filter as well as cool the air.

The results that may be obtained from air filtration, with or without cooling, are unfortunately disappointing. As pointed out by some of the early workers in this field (B. Z. Rappaport, *Tell Nelson and W. H. Welker,* The Journal, *May 28, 1932,* p. 1961; Tell Nelson, B. Z. Rappaport and W. H. Welker, *ibid,* May 6, 1933, p. 1385) patients with hay fever obtain a variable degree of relief while in the air-filtered room. The symptoms, even if completely relieved, recur in fifteen to forty-five minutes after the patient leaves the room. Severe hay fever is not readily relieved unless the patient remains in the room for hours. The symptoms of asthma require residence in an air-filtered room for twenty-four hours to several days before relief is obtained. Asthma will recur if the patient is exposed to pollen for a short period (about one hour in the average case). Therefore, unless it is possible for the patient to remain in an air-filtered room constantly, filtration alone is not usually sufficient to afford relief, especially in asthma. Patients who respond to treatment by hyposensitization so that the residual symptoms are mild are made more comfortable if the sleeping quarters are free of pollen.

VENEREAL WARTS

To the Editor:—A woman aged 28 has "venereal warts," which are spreading rapidly despite treatment. I find nothing on this subject in the index of The Journal for the past year. I shall appreciate an outline of the most efficient treatment for this condition. The patient is otherwise in good physical condition, condition of the blood is normal, urinalysis is negative, smears from vagina and urethra are negative, and she has no history of infection.

M.D., Utah.

Answer.—An effective method of removing venereal warts is to apply to them a solution of podophyllin, 25 per cent, in either 90 per cent alcohol or compound tincture of benzoin. Each wart or cluster of warts should be painted with the solution at intervals of five days or one week. Two or three such treatments usually are sufficient to eradicate most venereal warts.

One must avoid irritation of the surrounding normal skin by the escharotic agent. The patient should remain in the office until the medicine has dried, and then a protective coat of talcum should be applied to the warts and adjacent area before the patient moves about.

If the warts are situated in an area that it not easily accessible, it is sometimes necessary to anesthetize the patient and then destroy the warts by means of electrosurgery.

PSORIASIS

To the Editor:—What, if anything, can be done in the treatment and cure of psoriasis involving the palms and soles? Is psoriasis communicable?

M.D., New York.

Answer.—The treatment depends on the types of lesions, for psoriasis of the palms and soles occurs in several forms: sharply localized papules and patches similar to psoriasis on the elbows; bright red, diffuse areas involving the entire surface of each palm and sole; superficial erythematous areas or much thickened patches, perhaps with deep fissures, or the so-called pustular psoriasis. The nosologic position of the latter (pustular) type is still debatable, for some dermatologists consider it to be not psoriasis but a recalcitrant eruption due often to a focus of infection elsewhere in the body.

The treatment of psoriasis of the palms is similar to that for psoriasis elsewhere—with ointments, sometimes roentgen therapy or ultraviolet light and diet. Ointments containing salicylic acid 2 to 5 per cent and ammoniated mercury 3 to 10 per cent, tar preparations 3 to 5 per cent or anthralin 0.1 to 0.25 per cent are most favored. Weaker concentrations are used for superficial patches, the stronger concentrations for deep-seated and thickened lesions. The pustular type is the most resistant to treatment. In this type it is sometimes well to macerate the areas first with cool wet packs of solutions of aluminum subacetate 0.5 per cent, boric acid or potassium permanganate 1:3,000.

Roentgen therapy, if the dosage is kept within safe limits, is often effective for all types of psoriasis. However, psoriasis is likely to recur, and if roentgen therapy is instituted for each attack there is some danger of permanent injury to the tissues from the cumulative effect of the roentgen rays. In addition, a diet low in fats benefits some patients with psoriasis. It is well also to eliminate all foci of infection. Psoriasis is not contagious or communicable.

PENICILLIN ENHANCEMENT FACTOR

To the Editor:—There is some discussion regarding therapeutic effectiveness of penicillin G (crystalline) as compared to that of amorphous penicillin. A recent article in a pharmacy journal (Flack, H. L.: Status of Penicillin and Penicillin Dosage Forms, *Am. Profess. Pharmacist* 13:830 [Sept.] 1947) emphasizes some of these differences. The conclusion is that although crystalline penicillin G is more convenient to use, in that the solutions do not require refrigeration, nevertheless such purified products are lacking in the X or "Enhancement Factor," which apparently potentiates the action of penicillin in certain infections. As Flack indicates, most penicillin presently employed is crystalline G. If his conclusions are accurate, there are many infections which should be treated with amorphous penicillin rather than with the crystalline form. I would appreciate an analysis of this problem.

Robert G. Lehman, M.D., San Pedro, Calif.

Answer.—The so-called "enhancement factor" in amorphous penicillin was first described by Welch and his associates of the Food and Drug Administration, although details of their work have not yet been published. Confirmation of this work has been published by Hobby and her co-workers (Hobby, G. L.; Lenert, T. F., and Hyman, B.: *J. Bacteriol.* 54:305, 1947). The enhancement factor has not been identified and does not appear to be antibacterial when used alone. Administered with penicillin, it increases the apparent potency of penicillin against experimentally induced infections up to as much as five times, depending on the infecting organism. It has been found that not all lots of amorphous penicillin contain the enhancement factor, and, in fact, there may be a number of dissimilar substances which possess this property. Adequate clinical data on the use of the enhancement factor have not been published, and it is not possible to predict the practical importance of this discovery. The division of penicillin control and immunology of the Food and Drug Administration has stated informally that they will certify lots of penicillin claiming therapeutic benefit due to the presence of the enhancement factor only if the factor is demonstrably present in effective amounts. It is not believed that any such lots of penicillin have been certified as yet.

CONDUCTION DEAFNESS

To the Editor:—I recently saw a patient with bilateral conduction deafness who on squatting with his head low, or bending at the waist, for a minute to a minute and a half would regain hearing enough to detect a soft whisper. Ear drums appear normal and voluntary insufflation of auditory tubes produces no change in hearing. I can find no explanation for this. Is it possible that there is a poor contact between the plate of the stapes and the fenestra cochleae and that when he raises his intracranial pressure he also raises the intracochlear pressure and makes a better contact?

R. J. Antos, M.D., Phoenix, Ariz.

Answer.—The accumulation of noninflammatory serum in the middle ear spaces may result in the symptom described—the change in position being sufficient to move the fluid away from the oval and round windows, permitting the normal conduction of sound. The ear drums may appear normal unless magnification is used, in which case a fluid level may be visible or bubbles may be seen after inflation of the tube. Paracentesis of the tympanic membrane followed by inflation to blow out the fluid should result in improvement of the impaired hearing, provided there is no chronic obstruction of the eustachian tube from hypertrophied lymphoid tissue or an associated nasal allergy.

PROPYLTHIOURACIL

To the Editor:—If there is swelling of the thyroid during administration of propylthiouracil is it an indication for reduction of the dose or can it be disregarded?

C. F. Noe, M.D., Amana, Iowa.

Answer.—The thyroid gland frequently becomes a little larger and usually becomes harder during the administration of propylthiouracil. These changes in the gland may be disregarded and are not indications for reducing the dose.

JOURNALS ABSTRACTED IN THE CURRENT MEDICAL LITERATURE DEPARTMENT, MAY—AUGUST 1948

Titles have been listed or abstracts made of important articles in the following journals in the Current Literature Department of THE JOURNAL during the past four months. Any of the journals, except those starred, will be lent by THE JOURNAL to subscribers in continental United States and Canada and to members of the American Medical Association for a period not exceeding three days. Three journals may be borrowed at a time. No journals are available prior to 1937. Requests for periodicals should be addressed to the Library of the American Medical Association and should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Thus most of these journals are accessible to the general practitioner

SUBJECT INDEX

This is an index to all the reading matter in THE JOURNAL. In the Current Medical Literature Department only the articles which have been abstracted are indexed.

The letters used to explain in which department the matter indexed appears are as follows: "BI," Bureau of Investigation; "E," Editorial; "C," Correspondence; "OS," Organization Section; "ab," abstracts; the star (*) indicates an original article in THE JOURNAL.

This is a subject index and one should, therefore, look for the subject word, with the following exceptions: "Book Notices," "Deaths," "Medicolegal Abstracts" and "Societies" are indexed under these titles at the end of the letters "B," "D," "M," and "S." Matter pertaining to the Association is indexed under "American Medical Association." The name of the author, in brackets, follows the subject entry.

For author index page 1692.
